1 Lie algebras and groups	1	2d $\mathcal{N} = (1, 1)$	
1.1 Lie algebras	1	1d $\mathcal{N}=2$	
Complex simple Lie algebras		$egin{array}{ccc} ^{ m NLSM} & & & & \\ & & & & \\ & & & & \\ & & & & $	7
Roots and Weyl group Real simple Lie algebras		5.1 Two-dimensional CFT	7
Accidental isomorphisms		Virasoro algebra	'
ADE classification	0	$\mathcal{N} = 1$ super-Virasoro algebra	
1.2 Lie groups Basics	2	$\mathcal{N}=2$ super-Virasoro algebra $SW(3/2,2)$ super-Virasoro algebra	
Compact connected Lie groups		bc system	
Real connected simple Lie groups Spin and Pin groups		$eta\gamma$ system Liouville CFT	
Accidental isomorphisms		Minimal model	
Homotopy		Unitary minimal model	
1.3 Simple Lie superalgebras	3	$\mathcal{N} = 2$ minimal models	8
Classical Lie superalgebras Real forms of Lie superalgebras		5.2 3d gauge theories Chern-Simons term	O
Some isomorphisms		Magnetic global symmetry	
1.4 Lie supergroups	3	Contact term in $\langle JJ \rangle$ Action of $SL(2, \mathbb{Z})$	
1.5 Representations	3	5.3 Supergravity and strings	8
Complex dimensions of smalest irreps	4	String actions	Ü
2 Quantum field theory	4	Pure supergravities	
2.1 Generalities Yang-Mills term	4	M-theory Branes	
Theta term		Flat space brane configurations	
Chern—Simons term Boundaries and gauge redundancies		S-rule, brane creation Little string theory (LST)	
Loops		5.4 Integrable models	8
A redundant operator		Sine-Gordon model	0
An abelian $q$ -form symmetry Coleman-Mermin-Wagner		Relativistic quantum Toda chain	
2.2 Anomalies	4	6 Dualities	8
Continuous anomalies	-	$6.1 \text{ 4d } \mathcal{N} = 1 \text{ dualities}$	8
Fermion effective action Anomaly polynomial		IR duality Seiberg duality: SU with flavours	
Continuous gravitational anomaly		SO with fundamentals	
Discrete gravitational anomaly		USp with fundamentals Self-duality	
Mixed gauge-gravity anomaly	4	SU with flavours and adjoint	
2.3 Supersymmetric theories Vector	4	SU mixing two W	
Matter		Other 4d $\mathcal{N} = 1$ dualities 6.2 3d dualities	9
Superpotential term An accidental symmetry		Level-rank duality	Э
R-symmetry		Chern-Simons matter dualities	
Classical vacua		With scalars and fermions	0
2.4 Spinors	5	6.3 Field theory dualities	9
Clifford algebra Charge conjugation		6.4 String theory dualities	9
Reduced spinors			10
Flavour symmetries Products of spinor representations		7.1 Pseudo-Riemannian geometry Connection	10
3 Supersymmetry	5	The Levi-Civita connection	
3.1 Generalities		Killing vector	
			10
The Poincaré algebra	5		10
The Poincaré algebra Super-Poincaré algebra	Э	Structure group	10
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra	Э	Structure group Integrability The holonomy group	10
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction	Э	Structure group Integrability The holonomy group Spin structures	10
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved	Э	Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces	10
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved spaces		Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces Yau's theorem	
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved spaces 3.2 Explicit susy algebras	6	Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces Yau's theorem  8 Misc	11
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved spaces $\begin{array}{l} 3.2 \ \ \text{Explicit susy algebras} \\ \text{4d } \mathcal{N}=2 \\ \text{3d } \mathcal{N}=2 \end{array}$	6	Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces Yau's theorem 8 Misc 8.1 Special functions	
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved spaces $3.2 \; \text{Explicit susy algebras} \\ 4d \; \mathcal{N} = 2 \\ 3d \; \mathcal{N} = 2 \\ 3.3 \; \text{Spin} \leq 1 \; \text{supermultiplets} $		Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces Yau's theorem  8 Misc	11
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved spaces $\begin{array}{l} 3.2 \ \ \text{Explicit susy algebras} \\ \text{4d } \mathcal{N}=2 \\ \text{3d } \mathcal{N}=2 \end{array}$	6	Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces Yau's theorem  8 Misc 8.1 Special functions Multiple gamma function Plethystic exponential q-Pochhammer symbol	11
The Poincaré algebra Super-Poincaré algebra Example: M-theory algebra Lorentzian superconformal algebras Dimensional reduction Supersymmetry on symmetric curved spaces 3.2 Explicit susy algebras 4d $\mathcal{N}=2$ 3d $\mathcal{N}=2$ 3.3 Spin $\leq 1$ supermultiplets For 16 supercharges For 8 supercharges For 64 supercharges For 65 4 supercharges	6	Structure group Integrability The holonomy group Spin structures Symmetric spaces K3 surfaces Yau's theorem  8 Misc 8.1 Special functions Multiple gamma function Plethystic exponential q-Pochhammer symbol q-gamma (or basic gamma) function	11

#### $\S 1.1$ Lie algebras

Complex simple Lie algebras. Infinite series  $\mathfrak{a}_{n>1}$ ,  $\mathfrak{b}_{n>1}$ ,  $\mathfrak{c}_{n>1},\,\mathfrak{d}_{n>2}$  with  $\mathfrak{a}_1=\mathfrak{b}_1=\mathfrak{c}_1,\,\mathfrak{b}_2=\mathfrak{c}_2,\,\mathfrak{d}_2=\mathfrak{a}_1\oplus\mathfrak{a}_1,\,\mathfrak{d}_3=\mathfrak{a}_3.$  $\mathfrak{e}_6$  $e_7$ Five exceptions with dimensions 133248

Type	Dimension	Lie algebra
$egin{array}{c} \mathfrak{a}_n \ \mathfrak{b}_n \ \mathfrak{c}_n \ \mathfrak{d}_n \end{array}$	n(n+2) $n(2n+1)$ $n(2n+1)$ $n(2n-1)$	$\mathfrak{sl}(n+1,\mathbb{C}) = \{\text{traceless}\}$ $\mathfrak{so}(2n+1,\mathbb{C}) = \{\text{antisymmetric}\}$ $\mathfrak{sp}(2n,\mathbb{C}) = \{\begin{pmatrix} 0 & \mathbb{I}_n \\ -\mathbb{I}_n & 0 \end{pmatrix} \times \text{symmetric}\}$ $\mathfrak{so}(2n,\mathbb{C}) = \{\text{antisymmetric}\}$

Roots and Weyl group. The Weyl group has  $\prod_i d_i$  elements where  $d_i$  are degrees of fundamental invariants. (Below,  $\mathbb{I}_i$  denotes the *i*-th unit vector in  $\mathbb{Z}^n$  and  $1 \leq i \neq j \leq n$ .)

- $\mathfrak{a}_{n-1}$ : (note shifted rank) roots  $\mathbb{1}_i \mathbb{1}_i$ , simple roots  $\mathbb{1}_i \mathbb{1}_{i+1}$ . The Weyl group  $S_n$  permutes the  $\mathbb{1}_i$ . Fundamental invariants:  $x_1^k + \dots + x_n^k$  for  $2 \le k \le n$ .
- $\mathfrak{b}_n$ : roots  $\pm \mathbb{1}_i$  and  $\pm \mathbb{1}_i \pm \mathbb{1}_j$ , simple roots  $\mathbb{1}_i \mathbb{1}_{i+1}$  and  $\mathbb{1}_n$ . The Weyl group  $\{\pm 1\}^n \rtimes S_n$  permutes and changes signs of the  $\mathbb{1}_i$ . Fundamental invariants:  $x_1^{2k} + \cdots + x_n^{2k}$  for  $2 \le 2k \le 2n$ .
- $\mathfrak{c}_n$ : roots  $\pm 2\mathbb{1}_i$  and  $\pm \mathbb{1}_i \pm \mathbb{1}_j$ , simple roots  $\mathbb{1}_i \mathbb{1}_{i+1}$  and  $2\mathbb{1}_n$ . Same Weyl group and invariants as  $\mathfrak{b}_n$ .
- $\mathfrak{d}_n$ : roots  $\pm \mathbb{1}_i \pm \mathbb{1}_j$ , simple roots  $\mathbb{1}_i \mathbb{1}_{i+1}$  and  $\mathbb{1}_{n-1} + \mathbb{1}_n$ . The Weyl group  $\{\pm 1\}^{n-1} \rtimes S_n$  permutes the  $\mathbb{1}_i$  and changes an even number of signs. Fundamental invariants  $x_1 \cdots x_n$  and  $x_1^{2k} + \dots + x_n^{2k}$  for  $2 \le 2k \le 2n - 2$ .
- $\mathfrak{e}_{8} : \{ \pm \mathbb{1}_{i} \pm \mathbb{1}_{j} \} \cup \{ \frac{1}{2} \sum_{k=1}^{8} \epsilon_{k} \mathbb{1}_{k} \mid \epsilon_{k} = \pm 1, \prod_{k=1}^{8} \epsilon_{k} = -1 \},$ simple roots  $\mathbb{1}_{i} \mathbb{1}_{i+1}$  and  $\frac{1}{2} (-\mathbb{1}_{1} \dots \mathbb{1}_{5} + \mathbb{1}_{6} + \mathbb{1}_{7} + \mathbb{1}_{8}).$ The  $2^{14} 3^5 5^2 7 = 696729600$ -element Weyl group is  $O_8^+(\mathbb{F}_2)$ . Degrees of invariants are  $\{d_i\} = \{2, 8, 12, 14, 18, 20, 24, 30\},\$ with mnemonic 1 + (primes from 7 to 29).
- $\mathfrak{e}_7$ : roots  $\sum_{i=1}^8 a_i \mathbb{1}_i$  of  $\mathfrak{e}_8$  with  $a_1 = \sum_{i=2}^8 a_i$ , simple roots are those of  $\mathfrak{e}_8$  except  $\mathbb{1}_1 \mathbb{1}_2$ . The  $2^{10} \times 3^4 \times 5 \times 7 = 2903040$ element Weyl group is  $\mathbb{Z}_2 \times \mathrm{PSp}_6(\mathbb{F}_2)$ . Degrees of invariants
- simple roots are those of  $\mathfrak{e}_8$  except  $\mathbb{1}_1 - \mathbb{1}_2$  and  $\mathbb{1}_2 - \mathbb{1}_3$ . The  $2^7 3^4 5 = 51840$ -element Weyl group is Aut(PSp<sub>4</sub>( $\mathbb{F}_3$ )). Degrees of invariants are  $\{d_i\} = \{2, 5, 6, 8, 9, 12\}.$ 
  - $f_4$ : roots  $\pm 1_i$ ,  $\pm 1_i \pm 1_j$ ,  $\frac{1}{2}(\pm 1_1 \pm 1_2 \pm 1_3 \pm 1_4)$ , simple roots  $\mathbb{1}_1 - \mathbb{1}_2$ ,  $\mathbb{1}_2 - \mathbb{1}_3$ ,  $\mathbb{1}_3$ ,  $-\frac{1}{2}(\mathbb{1}_1 + \mathbb{1}_2 + \mathbb{1}_3 + \mathbb{1}_4)$ . It has an
  - 1152-element Weyl group and  $\{d_i\} = \{2, 6, 8, 12\}$ .  $\mathfrak{g}_2$ : 12 roots  $e^{2\pi i k/6}$ ,  $e^{2\pi i (2k+1)/12}\sqrt{3} \in \mathbb{C}$  for  $0 \le k < 6$ , simple roots 1 and  $e^{5\pi i/6}\sqrt{3}$ . The 12-element Weyl group is the dihedral group  $D_6$ , and  $\{d_i\} = \{2, 6\}$ .

The Coxeter number  $h(\mathfrak{g}) = (\dim \mathfrak{g} / \operatorname{rank} \mathfrak{g}) - 1$  is the largest  $d_i$ . A Coxeter element is the product of all simple reflections, in any order. Its eigenvalues  $e^{2\pi i(d_i-1)/h}$  come in conjugate pairs.

A real simple Lie algebra is a complex algebra (see above) or a real form of it. Let  $\mathfrak{sp}(m,n) = \mathfrak{usp}(2m,2n) = \mathfrak{u}(m,n,\mathbb{H}),$  $\mathfrak{su}^*(2n) = \mathfrak{sl}(n,\mathbb{H}) = \{ \operatorname{Re} \operatorname{Tr} M = 0 \text{ in } \mathfrak{gl}(n,\mathbb{H}) \} \simeq \mathfrak{gl}(n,\mathbb{H})/\mathbb{R},$  $\mathfrak{so}^*(2n) = \mathfrak{o}(n, \mathbb{H})$ . A Lie algebra is called compact if it exponentiates to a compact Lie group. In  $\mathfrak{e}_{r(s)}$ , s is the number of (non-compact) – (compact) generators. The maximal compact subalgebra of a complex algebra is its compact real form.

#### §1.2 Lie groups

**Basics.** The identity component  $G_0$  is a normal subgroup:  $G/G_0$  is the group of components. The maximal compact subgroup K is unique up to conjugation.

Every compact connected Lie group K is a quotient of  $\mathrm{U}(1)^n \times \prod_{i=1}^m K_i$  by a finite subgroup  $\Gamma$  of its center, where  $K_i$ are simple, compact, simply-connected, connected. Then  $\pi_1(K)/\mathbb{Z}^n \simeq \Gamma$  for some embedding  $\mathbb{Z}^n \hookrightarrow \pi_1(K)$ , and the center of K is  $Z(K) = (U(1)^n \times \prod_{i=1}^m Z(K_i)) / \Gamma$ .

Center of all such  $K_i$ :  $Z(SU(n)) = \mathbb{Z}_n$ ,  $Z(USp(2n)) = \mathbb{Z}_2$ ,  $Z(\operatorname{Spin}(n \geq 3)) = (\mathbb{Z}_2 \text{ for } n \text{ odd}, \mathbb{Z}_4 \text{ for } n/2 \text{ odd}, \mathbb{Z}_2^2 \text{ otherwise}),$  $Z(\mathcal{E}_{6(-78)}) = \mathbb{Z}_3, \ Z(\mathcal{E}_{7(-133)}) = \mathbb{Z}_2, \text{ while } \mathcal{E}_{8(-248)}, \ \mathcal{F}_{4(-52)},$  $G_{2(-14)}$  have no center.

Named quotients:  $SO(n) = Spin(n)/\mathbb{Z}_2$  and PG = G/Z(G)for G = SU, USp, SO (also U, GL, SL). The other two quotients  $\operatorname{Spin}(4n)/\mathbb{Z}_2$  have no name.

Real connected simple Lie groups are the simply-connected G (classified by simple Lie algebras) and their quotients by a subgroup  $\Gamma \subset Z(G)$  of the center; equivalently, covers of the center-free  $G_{\rm cf} = \widetilde{G}/Z(\widetilde{G})$ . One has  $\pi_1(\widetilde{G}/\Gamma) = \Gamma$ and  $Z(\widetilde{G}/\Gamma) = Z(\widetilde{G})/\Gamma$ . The algebraic universal cover  $\widetilde{G}_{alg}$ (largest with a faithful finite-dimensional representation) may be a quotient of  $\widetilde{G}$ . We define  $\pi_1^{\text{alg}}(\widetilde{G}_{\text{alg}}/\Gamma) = \Gamma$ . For each real simple Lie algebra  $\mathfrak{g}$ , we tabulate:  $G_{\rm cf}$  as a quotient of  $\widetilde{G}_{\rm alg}$ ; the (topological)  $\pi_1$ ; the real rank  $r_{\text{Re}}$ ; and the maximal compact subgroup  $K \subset G_{cf}$ . Below,  $\iota(l) = (1 \text{ for } l \text{ odd}, 2 \text{ otherwise}),$ p+q=n with  $p,q\geq 1,$  and 2k=n when n is even. For  $\mathfrak{sl}(2)$ use SU(2) = Sp(2),  $SL(2, \mathbb{R}) = Sp(2, \mathbb{R})$ ,  $SL(2, \mathbb{C}) = Sp(2, \mathbb{C})$ .

Spin and Pin groups. SO(n) has a double cover Spin(n). Since  $\pi_0(O(n)) = \mathbb{Z}_2$  there are two double covers:  $Pin_+(n)$  in which a reflection R obeys  $R^2 = 1$ , and  $Pin_-(n)$  in which  $R^2 = (-1)^F$ . For  $p, q \ge 1$ ,  $\pi_0(O(p,q)) = \pi_0(O(p)) \times \pi_0(O(q)) = \mathbb{Z}_2^2$ ; the identity component  $SO_+(p,q)$  has a double cover Spin(p,q). The eight double covers of O(p,q) differ in whether  $R^2$ ,  $T^2$  and  $(RT)^2$  are +1 or  $(-1)^F$ .

Accidental isomorphisms (real reductive Lie groups)  $\mathbb{R}/\mathbb{Z} = U(1)$ ;  $SU(2) = Spin(3) \twoheadrightarrow SO(3)$ ; . . .

**Homotopy.** Any connected Lie group is homeomorphic to its maximal compact subgroup K times a Euclidean space  $\mathbb{R}^p$ . All  $\pi_{j\geq 1}(K)$  are abelian and finitely generated,  $\pi_2(K)=0$ ,  $\pi_3(K)=\mathbb{Z}^m$  where m counts simple factors in a finite cover  $\mathrm{U}(1)^n\times\prod_{i=1}^m K_i\twoheadrightarrow K$ , and  $\pi_j(K)=\prod_{i=1}^m \pi_j(K_i)$  for  $j\geq 2$ .

For any G there exists  $\prod_{i=1}^{\operatorname{rank} G} S^{2d_i-1} \to G$  which induces isomorphisms of rational (i.e., torsion-free part of) homotopy/cohomology groups where  $d_i$  are the degrees of fundamental invariants. For compact simple K,

Group $(2d_i - 1)$	$E_6$ 3, 9, 11, 15, 17, 23
$\begin{array}{c} A_n & 3, 5, \dots, 2n+1 \\ B_n, C_n & 3, 7, \dots, 4n-1 \\ D_n & 3, 7, \dots, 4n-5, 2n-1 \end{array}$	$E_7 \ 3, 11, 15, 19, 23, 27, 35 \\ E_8 \ 3, 15, 23, 27, 35, 39, 47, 59 \\ F_4 \ 3, 11, 15, 23 \\ G_2 \ 3, 11$

 $\pi_{j\geq 2}(G)$  has a factor  $\mathbb{Z}$  for each  $S^j$  above, and some torsion. Explicitly,  $\pi_j(\mathrm{SU}(n))$  is  $\mathbb{Z}$  for odd j<2n, 0 for even j<2n, and is pure torsion for  $j\geq 2n$ . Similarly,  $\pi_{j<4n+2}(\mathrm{USp}(2n))$  is  $\mathbb{Z}$  for  $j\equiv 3,7 \bmod 8$ ,  $\mathbb{Z}_2$  for  $j\equiv 4,5 \bmod 8$ , and 0 otherwise.

# §1.3 Simple Lie superalgebras

Classical Lie superalgebras: the bosonic algebra acts on the fermionic generators in a completely reducible representation. This excludes Cartan-type superalgebras  $\mathfrak{w}(n)$ ,  $\mathfrak{s}(n)$ ,  $\tilde{\mathfrak{s}}(n)$  and  $\mathfrak{h}(n)$ . In this table,  $m,n\geq 1$  and we do not list purely bosonic Lie algebras. The factor  $\mathbb{C}$  of  $\mathfrak{sl}(m|n)$  must be removed if m=n.

	Bosonic algebra	Fermionic repr.
$\mathfrak{sl}(m n)$	$\mathfrak{sl}(m,\mathbb{C})\oplus\mathfrak{sl}(n,\mathbb{C})\oplus\mathbb{C}$	$(m,\overline{n})\oplus(\overline{m},n)$
$\mathfrak{osp}(m 2n)$	$\mathfrak{so}(m,\mathbb{C})\oplus\mathfrak{sp}(2n,\mathbb{C})$	(m,2n)
$\mathfrak{d}(2,1,lpha)$	$\mathfrak{sl}(2,\mathbb{C})^3$	(2, 2, 2)
$\mathfrak{f}(4)$	$\mathfrak{so}(7,\mathbb{C})\oplus\mathfrak{sl}(2,\mathbb{C})$	(8,2)
$\mathfrak{g}(3)$	$\mathfrak{g}_2\oplus\mathfrak{sl}(2,\mathbb{C})$	(7,2)
$\mathfrak{p}(m)$	$\mathfrak{sl}(m+1,\mathbb{C})$	$\mathrm{sym} \oplus (\mathrm{antisym})^*$
$\mathfrak{q}(m)$	$\mathfrak{sl}(m+1,\mathbb{C})$	adjoint

Real forms of Lie superalgebras, starting from their compact form (p=q=0).  $\mathfrak{p}(m)$  has no compact form. Here,  $m, n \geq 1, 0 \leq p \leq m/2, 0 \leq q \leq n/2$ . The forms  $\mathfrak{su}^*$ ,  $\mathfrak{osp}^*$ ,  $\mathfrak{q}^*$  only exist for even rank;  $\mathfrak{sl}'$  only if m=n.

Real form	Bosonic algebra
	$\begin{array}{c} \mathfrak{su}(m-p,p) \oplus \mathfrak{su}(n-q,q) \oplus \mathfrak{u}(1)^{\ddagger} \\ \mathfrak{sl}(m,\mathbb{R}) \oplus \mathfrak{sl}(n,\mathbb{R}) \oplus \mathfrak{so}(1,1)^{\ddagger} \\ \mathfrak{sl}(n,\mathbb{C}) \\ \mathfrak{su}^*(m) \oplus \mathfrak{su}^*(n) \oplus \mathfrak{so}(1,1)^{\ddagger} \end{array}$
$ \mathfrak{osp}(m-p,p 2n) \\  \mathfrak{osp}^*(m 2n-2q,2q) \ (m ) $	$\mathfrak{so}(m-p,p)\oplus\mathfrak{sp}(2n,\mathbb{R})$ $\mathfrak{so}^*(m)\oplus\mathfrak{usp}(2n-2q,2q)^\P$
$\mathfrak{d}^p(2,1,lpha)$ §	$\mathfrak{so}(4-p,p)\oplus\mathfrak{sl}(2,\mathbb{R})\;(p=0,1,2)$
$\mathfrak{f}^p(4) \text{ for } p = 0, 3$ $\mathfrak{f}^p(4) \text{ for } p = 1, 2$	$\mathfrak{so}(7-p,p)\oplus\mathfrak{sl}(2,\mathbb{R}) \ \mathfrak{so}(7-p,p)\oplus\mathfrak{su}(2)$
$g_s(3) \text{ for } s = -14, 2$	$\mathfrak{g}_{2(s)}\oplus\mathfrak{sl}(2,\mathbb{R})$
$\mathfrak{p}(m)$	$\mathfrak{sl}(m+1,\mathbb{R})$
$\begin{array}{c} \mathfrak{u}\mathfrak{q}(m-p,p) \\ \mathfrak{q}(m) \\ \mathfrak{q}^*(m) \pmod{0} \end{array}$	$\mathfrak{su}(m+1-p,p)$ $\mathfrak{sl}(m+1,\mathbb{R})$ $\mathfrak{su}^*(m+1)$

- <sup>‡</sup> For m = n,  $\mathfrak{u}(1)$  and  $\mathfrak{so}(1,1)$  factors are absent. Additionally, one can project down to a single bosonic factor.
  - ¶  $\wedge$  A real form of  $\mathfrak{osp}(2|2,\mathbb{C}) = \mathfrak{sl}(2|1,\mathbb{C})$  is missing.
- § The three  $\mathfrak{sl}(2)$  bosonic factors of  $\mathfrak{d}(2,1,\alpha)$  appear with weights 1,  $\alpha$  and  $-1-\alpha$  in fermion anticommutators. For  $\mathfrak{d}^0$  and  $\mathfrak{d}^2$ ,  $\alpha$  is real. For  $\mathfrak{d}^1$ ,  $\alpha=1+ia$  with a real.

Some isomorphisms:  $\mathfrak{su}(1,1|1) = \mathfrak{sl}(2|1) = \mathfrak{osp}(2|2)$  and  $\mathfrak{su}(2|1) = \mathfrak{osp}^*(2|2,0)$  and  $\mathfrak{d}^p(2,1,\alpha=1) = \mathfrak{osp}(4-p,p|2)$  and  $\mathfrak{osp}(6,2|4) = \mathfrak{osp}^*(8|4)$ .

# §2 Quantum field theory

# §2.1 Generalities

**Yang–Mills term.** A gauge group is a compact reductive Lie group G such as  $(SU(3) \times SU(2) \times U(1))/\mathbb{Z}_6$ . The gauge kinetic term is  $\mathcal{L}_{SYM} = g^{-2} \operatorname{Tr} F \wedge \star F$ , with one real gauge coupling g per simple factor.

**Theta term** in even dimension:  $\theta \operatorname{Tr} F^{\wedge (d/2)}$  with  $\theta$  periodic. In 4d,  $\theta$  and g combine to  $\tau = \theta/(2\pi) + 4\pi i/g^2$ .

**Chern–Simons term** in 3d:  $k \operatorname{Tr}(A \wedge dA + \frac{2}{3}A \wedge A \wedge A)$  with k quantized (normalization missing).

Boundaries and gauge redundancies. On a non-compact spacetime one can consider the group of gauge redundancies with various boundary conditions. Let  $H \subset F$  be the constant transformations included as gauge redundancies (including constant gauge transformations by  $H \cap G$ ). The Higgs branch flavour symmetry is then  $\{x \in F \mid xG = Gx, xH = Hx\}/H$ .

**Loops.** A Polyakov loop is just a Wilson loop in the fundamental representation and wrapping the time direction.

**A redundant operator** is  $\mathcal{O}$  such that  $\langle \mathcal{O}(p)\mathcal{O}(-p)\rangle$  is polynomial in the momentum p; equivalently,  $\langle \mathcal{O}(x)\mathcal{O}(y)\rangle$  vanishes at separated points.

An abelian q-form symmetry [1412.5148] (for q=0 this is a standard flavor symmetry and can be nonabelian) is a (q+1)-form current J such that  $\mathrm{d} \star J = 0$ ; it couples as  $\int B \wedge \star J$  to a background (q+1)-form gauge field B with gauge transformation  $B \to B + \mathrm{d} \Lambda$ .

The conserved charge  $Q(\Sigma) = \int_{\Sigma} \star J$  is measured along a (d-1-q)-cycle  $\Sigma$ . Charged operators are supported on q-cycles linking  $\Sigma$ ; charged excitations are dynamical q-branes intersecting  $\Sigma$  transversally. The symmetry is U(1) rather than  $\mathbb{R}$  if all  $Q(\Sigma) \in \mathbb{Z}$  so all  $\int_{\Sigma'} d\Lambda$  and  $\int_{\Sigma''} dB \in 2\pi\mathbb{Z}$ .

A q-form symmetry may emerge in the IR. The partition function Z[B] may suffer shifts under  $B \to B + \mathrm{d}\Lambda$ : such a 't Hooft anomaly prevents gauging (making B dynamical); it is an RG invariant hence matches in UV and IR.

**Coleman–Mermin–Wagner** (see [1802.07747] for p-forms) Spontaneous symmetry breaking of continuous p-form symmetry can only happen for D > p+2 (p+1 for discrete symmetries). The IR theory has massless p-form Nambu–Goldstone bosons.

## §2.2 Anomalies

Continuous anomalies in d=2n, in (n+1)-point functions of currents: (n+1)-gon fermion loop, summed over fermions. Forbid simultaneous nontrivial backgrounds for all n+1 symmetries. Anomaly with (n+1) gauge currents  $\Longrightarrow$  theory is sick. Anomaly with n gauge, one flavour  $\Longrightarrow$  classical flavour symmetry fails at one-loop,  $D_{\mu}J^{\mu} \sim \text{Tr}(\mathrm{d}A_1 \wedge \cdots \wedge \mathrm{d}A_n) + O(A^{n+1})$ .

Fermion effective action  $\Gamma[A]$  defined by  $\exp(-\Gamma[A]) = \int D\bar{\chi} D\psi \exp(-\int d^4x \bar{\chi} i \not D \gamma_- \psi)$  always has gauge-invariant and diffeomorphism-invariant real part but varies by the imaginary  $D_{\mu}(\delta\Gamma/\delta A_{\mu}) = D_{\mu}\langle J^{\mu}\rangle$  and  $D_{\mu}(\delta\Gamma/\delta g_{\mu\nu}) = \frac{1}{2}D_{\mu}\langle T^{\mu\nu}\rangle$ , nonzero in case of anomaly.

Anomaly polynomial: formal (d+2)-form built from field strengths F and Riemann R two-forms, traced.

Continuous gravitational anomaly. Spin(1, d-1) plus CPT only has complex representations for d=4k+2: for other even d, CPT exchanges chirality so we cannot have a single Weyl spinor. Focus on d=1+(4k+1), Weyl fermions of spin  $\frac{1}{2}$  and  $\frac{3}{2}$  and self-dual 2k+1 form. In 10d, unique theory with anomaly cancellation between fields of different spins: IIB supergravity. Above 10d, only same spins can cancel.

**Discrete gravitational anomaly.** In d=8k and d=8k+1, single Majorana spinors cannot be given mass (but pairs can). It turns out that coupling an odd number of spin  $\frac{1}{2}$  Majorana fermions to gravity is inconsistent.

Mixed gauge-gravity anomaly (or flavour-gravity) corresponds to  $(\frac{1}{2}d+1)$ -gons fermion loops with an even number of stress-tensors and some currents.

# §2.3 Supersymmetric theories

**Vector.** Yang-Mills, theta, Chern-Simons terms have super-symmetric completion. Additionally, FI parameter, real for 4 supercharges, triplet for 8 supercharges. Dimensionless in 2d, the FI parameter combines with the theta angle.

**Matter.** For 16 supercharges, none. For 8 supercharges, symplectic representation  $V \simeq \mathbb{H}^n$  namely  $G \to F = \mathrm{USp}(2n)$ . For 4 supercharges, unitary representation  $V \simeq \mathbb{C}^n$  namely  $G \to F = \mathrm{U}(n)$ . Canonical kinetic term for bosons:  $D_{\mu}\phi_i D^{\mu}\phi_i$ .

Superpotential term. For 4 supercharges,  $\int d^2\theta W$  gives a potential for scalars and Yukawa-type interactions. W is holomorphic in chiral fields and in couplings seen as background fields. Example: the kinetic term  $\operatorname{Im} \int d^2\theta [\tau W_{\alpha}^2]$  of an abelian gauge field:  $W_{\alpha}^2$  is a chiral field so  $\tau$  is the background value of a chiral field.

An accidental symmetry is a flavour symmetry of the IR but not of the UV.

**R-symmetry.** In 2d and higher the IR R-symmetry is part of the superconformal algebra, rather than an outer automorphism of it. The manifest (UV) R-symmetry can be a mixture of the IR R-symmetry and of a flavour symmetry:  $R_{\rm UV} \subset R_{\rm IR} \times F$ . For nonabelian R-symmetry that flavour symmetry must be accidental as it does not commute with  $R_{\rm UV}$ . For abelian R-symmetry the mixing is continuous; assuming no accidental flavour symmetries it is fixed in 4d  $\mathcal{N}=1$  by a-extremization, in 3d  $\mathcal{N}=2$  by  $Z_{S^3}$ -extremization, in 2d  $\mathcal{N}=(0,2)$  by c-extremization.

Vector multiplet scalars and gauge field are  $U(1)_R$  neutral. For chirals,  $\Delta \geq \frac{1}{2}(d-1)|R|$  at the fixed point.

Classical vacua: Coulomb, Higgs and mixed branches. Coulomb branch ( $\mathfrak g$  modulo conjugation by G) parametrized by vector multiplet scalars, larger in 3d due to monopoles, can be lifted by quantum effects. For 4 supercharges, Higgs branch parametrized by chiral multiplet scalars: Kähler quotient R//G. For 8 supercharges, Higgs branch parametrized by hypermultiplet scalars: hyper-Kähler quotient  $\widetilde{R}//G$ . The Higgs branch has flavour symmetry  $\{x \in F \mid xG = Gx\}/G$  normalizer of G in  $F = \mathrm{U}(R)$  or  $F = \mathrm{USp}(\widetilde{R})$  modulo G. Background vector multiplet scalars (real/twisted masses) reduce the Higgs and mixed branches to fixed points of corresponding flavour symmetries.

# **§2.4** Spinors (e.g. [hep-th/9910030])

Clifford algebra. Let  $h_{ab}$  be diagonal with s '+1' and t '-1', and d=s+t. The Clifford algebra  $\{\Gamma_a,\Gamma_b\}=2h_{ab}$  has real dimension  $2^d$  and is isomorphic to a matrix algebra  $M_{2^\#}(\bullet)$  with

Charge conjugation.  $(-\eta)\Gamma_a^T = \mathcal{C}\Gamma_a\mathcal{C}^{-1}$  are conjugate for  $\eta=\pm 1$  because they obey the same algebra. Get  $\mathcal{C}^T=-\varepsilon\mathcal{C}$  with  $\varepsilon=\pm 1$  by transposing twice. Let  $\Gamma^{(n)}=\Gamma_{a_1...a_n}$ . Using  $\left(\mathcal{C}\Gamma^{(n)}\right)^T=-\epsilon(-)^{n(n-1)/2}(-\eta)^n\mathcal{C}\Gamma^{(n)}$  find which  $n \mod 4$  give symmetric  $\mathcal{C}\Gamma^{(n)}$ . The sum of  $\binom{d}{n}$  must be  $2^{\lfloor d/2 \rfloor}(2^{\lfloor d/2 \rfloor}+1)/2$ . This fixes  $\epsilon,\eta$ . Odd d require  $\eta=(-1)^{d(d+1)/2}$  to preserve  $\Gamma^{(d)}$ . Even d allow two choices of signs: consult the rows  $d\pm 1$ .

$d \bmod 8$	n	$\epsilon$	$\eta$
$0_{\overline{2}}$ 1	0, 1	-1	-1
$\frac{2}{4}$ 3	1, 2	+1	+1
4\5	2, 3	+1	-1
$0\frac{6}{1}$ 7	0, 3	-1	+1

Reduced spinors.  $M_{ab} \in \mathfrak{so}(s,t)$  acts as  $\gamma_a \gamma_b$  on representations of the Clifford algebra. But the  $2^{\lceil d/2 \rceil}$ -dimensional representation is not irreducible as a representation of  $\mathfrak{so}(s,t)$ .

In even d, Weyl (or chiral) spinors  $\Gamma^{(d)}\lambda=\pm\lambda$  have  $2^{d/2-1}$  real components. Let B be defined by  $\Gamma_a^*=-\eta(-1)^tB\Gamma_aB^{-1}$ . Majorana spinors  $\lambda^*=B\lambda$  exist for  $s-t\equiv 0,\pm 1,\pm 2$  mod 8; the case  $s-t\equiv \pm 2$  requires  $\eta=\mp(-1)^{d/2}$ . When  $s-t\equiv 3,4,5,$  a set of 2n spinors can be symplectic Majorana:  $(\lambda^I)^*=B\Omega_{IJ}\lambda^J$  for  $\Omega=((0,\mathbb{1}_n);(-\mathbb{1}_n,0))$ . (Symplectic) Majorana–Weyl spinors exist for  $s-t\equiv 0,4$  mod 8. The table also includes the real dimension of the minimal spinor.

d t =	≡ 0	1	2	$3 \bmod 4$
1 (D 2) M	1	M 1		
$2 (W 2) M^{-}$	2	MW 1	$M^+$ 2	
3 (D 4) s	4	M = 2	M = 2	s 4
4 (W 4) sW	4	$M^+$ 4	MW 2	$\mathrm{M}^-$ 4
5 (D 8) s	8	s 8	M = 4	M = 4
$6 \text{ (W 8) } \text{M}^+$	8	sW = 8	$M^-$ 8	MW = 4
7 (D 16) M	8	s 16	s 16	M 8
8 (W16) MW	8	$M^{-}$ 16	sW = 16	$M^{+}$ 16
9 (D32) M	16	M 16	s 32	s 32
$10 \text{ (W32) } \text{M}^-$	32	MW 16	$M^{+}$ 32	sW 32
$11 \; (D \; 64) \; s$	64	M = 32	M = 32	s 64
12 (W64) sW	64	$M^{+}$ 64	MW 32	$M^{-}$ 64

Flavour symmetries of N minimal spinors. This is also the R-symmetry of the N-extended superalgebra. For (symplectic) Majorana Weyl spinors, specify  $N=(N_L,N_R)$  left/right-handed.

$$\mathbf{M} \begin{cases} \mathfrak{u}(N) & \text{if } d \text{ even} \\ \mathfrak{so}(N) & \text{if } d \text{ odd} \end{cases}$$
 $\mathbf{MW} : \mathfrak{so}(N_L) \times \mathfrak{so}(N_R)$ 
 $\mathbf{s} : \mathfrak{usp}(2N)$ 
 $\mathbf{sW} : \mathfrak{usp}(2N_L) \times \mathfrak{usp}(2N_R)$ 

E.g., Lorentzian 6d (2,0) has  $\mathfrak{usp}(4) \times \mathfrak{usp}(0)$  R-symmetry.

**Products of spinor representations.** For odd d = 2m + 1, let  $\mathcal{S}$  be a spinor representation of complex dimension  $2^m$ . The symmetric product  $S^2\mathcal{S}$  consists of k-forms with  $k \equiv m \mod 4$ . Since k-forms and (d-k)-forms are the same representation, other descriptions can be given. For the antisymmetric product  $\Lambda^2\mathcal{S}$ , take  $k \equiv m-1 \mod 4$ . See the list of forms in the table.

$d$ $\dim_{\mathbb{C}} \mathcal{S}$	1 1	3 2	5 4	7 8	9 16	11 32
$S^2 \mathcal{S} $ $\Lambda^2 \mathcal{S}$	0	1 0	$   \begin{array}{c}     2 \\     0, 1   \end{array} $		0, 1, 4 2, 3	1, 2, 5 $0, 3, 4$

For even d=2m, let  $\mathcal{S}_{\pm}$  be the Weyl spinor representations of complex dimension  $2^{m-1}$ . Then

$$S^{2}(\mathcal{S}_{+} \oplus \mathcal{S}_{-}) = S^{2}\mathcal{S}_{+} \oplus (\mathcal{S}_{+} \otimes \mathcal{S}_{-}) \oplus S^{2}\mathcal{S}_{-}$$
$$\Lambda^{2}(\mathcal{S}_{+} \oplus \mathcal{S}_{-}) = \Lambda^{2}\mathcal{S}_{+} \oplus (\mathcal{S}_{+} \otimes \mathcal{S}_{-}) \oplus \Lambda^{2}\mathcal{S}_{-}$$

The tensor product  $S_+ \otimes S_-$  consists of (m-1-2j)-forms for  $0 \leq j \leq (m-1)/2$ . The symmetric products  $S^2 S_{\pm}$  decompose into the (anti)-self-dual m-forms (denoted  $m^{\dagger}$ ) and (m-4j)-forms for  $0 < j \leq m/4$ . The antisymmetric products  $\Lambda^2 S_{\pm}$  decompose into (m-2-4j)-forms for  $0 \leq j \leq (m-2)/4$ .

d	2	4	6	8	10	12
$\dim_{\mathbb{C}}\mathcal{S}_{\pm}$	1	2	4	8	16	32
$S^2S_{\pm}$	$1^{\dagger}$	$2^{\dagger}$	$3^{\dagger}$	$0,4^{\dagger}$	$1,5^{\dagger}$	$2,6^{\dagger}$
$\Lambda^2 \mathcal{S}_\pm$		0	1	2	3	0, 4
$\mathcal{S}_+ \otimes \mathcal{S}$	0	1	0, 2	1, 3	0, 2, 4	1, 3, 5

# §3 Supersymmetry

# §3.1 Generalities

The Poincaré algebra is  $\mathbb{R}^{s,t} \rtimes \mathfrak{so}(s,t)$ , the semi-direct product of translations by rotations. Namely,  $[P_a,P_b]=0$ ,  $[M_{ab},P_c]=2ih_{c[a}P_{b]}$ , and  $[M_{ab},M^{cd}]=4ih_{[a}^{[c}M_{b]}^{d]}$ .

Super-Poincaré algebra. Add supercharges in some spinor representation Q of the Poincaré algebra (so  $[P_a,Q]=0$ ). Their anticommutator transforms in the representation  $S^2Q$  and should include the one-form P. Depending on s,t they can include other k-forms Z, called central charges because [P,Z]=[Z,Z]=0. The super-Poincaré algebra is  $((\mathbb{R}^{s,t}\times Z).Q)\times(\mathfrak{so}(s,t)\times R)$ , where the R-symmetry acts on Q. This Lie superalgebra is graded:  $\operatorname{gr}(\mathbb{R}^{s,t}\times Z)=-2$ ,  $\operatorname{gr}(Q)=-1$ , and  $\operatorname{gr}(\mathfrak{so}(s,t)\times R)=0$ . The supertranslations consist of  $(\mathbb{R}^{s,t}\times Z).Q$ .

**Example:** M-theory algebra. d=10+1 super-Poincaré algebra with Q= Majorana. Since  $S^2Q$  has 1, 2, and 5-forms, there are 2-form and 5-form central charges  $Z_{(2)}$  and  $Z_{(5)}$  (under which M2 and M5 branes are charged):

$$\begin{aligned} \{Q_{\alpha},Q_{\beta}\} &= (\gamma^M C)_{\alpha\beta} P_M + \frac{1}{2} (\gamma_{MN} C)_{\alpha\beta} Z_{(2)}^{MN} \\ &+ \frac{1}{5!} (\gamma_{MNPQR} C)_{\alpha\beta} Z_{(5)}^{MNPQR} \end{aligned}$$

Altogether the M-theory algebra is  $\mathfrak{osp}(1|32)$ .

**Lorentzian superconformal algebras** are the same as super  $AdS_{d+1}$ . The bosonic part is  $\mathfrak{so}(d,2)$  and R-symmetries. As a supermatrix:  $\begin{pmatrix} \mathfrak{so}(d,2) & Q+S \\ Q-S & R \end{pmatrix}$  or  $\begin{pmatrix} R & Q+S \\ Q-S & \mathfrak{so}(d,2) \end{pmatrix}$ . Note that  $\{Q,S\}$  contains R. For d=2, the finite conformal algebra is  $\mathfrak{so}(2,2)=\mathfrak{so}(2,1)\oplus\mathfrak{so}(2,1)$ , sum of two d=1 algebras, so the superalgebra is sum of two d=1 superalgebras.

$\overline{d}$	Superalgebra	R-symm (compact)	#Q+#S
1	$\mathfrak{osp}(N 2)$	$\mathfrak{o}(N)$	$\frac{n \cdot \mathbf{v} \cdot n}{2N}$
1	$\mathfrak{su}(N 1,1)$	$\mathfrak{su}(N) \oplus \mathfrak{u}(1) \text{ for } N \neq 2$	4N
	$\mathfrak{su}(2 1,1)$	$\mathfrak{su}(2)$	8
	$\mathfrak{osp}(4^* 2N)$	$\mathfrak{su}(2) \oplus \mathfrak{usp}(2N)$	8N
	$\mathfrak{g}_{-14}(3)$	$\mathfrak{g}_{2(-14)}$	14
	$\mathfrak{f}^0(4)$	$\mathfrak{so}(7)$	16
	$\mathfrak{d}^0(2,1,lpha)$	$\mathfrak{su}(2) \oplus \mathfrak{su}(2)$	8
3	$\mathfrak{osp}(N 4)$	$\mathfrak{so}(N)$	4N
4	$\mathfrak{su}(2,2 N)$	$\mathfrak{su}(N) \oplus \mathfrak{u}(1) \text{ for } N \neq 4$	8N
	$\mathfrak{su}(2,2 4)$	$\mathfrak{su}(4)$	32
5	$f^2(4)$	$\mathfrak{su}(2)$	16
6	$\mathfrak{osp}(8^* N)$	$\mathfrak{usp}(N)$ $(N \text{ even})$	8N

**Dimensional reduction** of Lorentzian supersymmetry algebras. The 1d column gives the number of real supercharges.

10d	6d	5d	4d	3d	2d	1d
$\mathcal{N} = (1,0)$	(1, 1)					
	(1, 0)	1	2	4	(4, 4)	8
			1	2	(2, 2)	4

Supersymmetry on symmetric curved spaces  $4d \mathcal{N} = 2$  supersymmetry on  $S^4$  is  $\mathfrak{osp}(2|4)$ .  $2d \mathcal{N} = (2,2)$  supersymmetry on  $S^2$  is  $\mathfrak{osp}(2|2)$ .

# §3.2 Explicit supersymmetry algebras

4d 
$$\mathcal{N}=2$$
.  $\{Q_{\alpha}^{A}, \overline{Q}_{\dot{\alpha}}^{B}\}=\epsilon^{AB}P_{\alpha\dot{\alpha}}; 0=\{Q_{\alpha}^{A}, Q_{\beta}^{B}\}=\{\overline{Q}_{\dot{\alpha}}^{A}, \overline{Q}_{\dot{\beta}}^{B}\}.$ 
3d  $\mathcal{N}=2$ .  $\{Q_{\alpha}, \overline{Q}_{\beta}\}=2\sigma_{\alpha\beta}^{\mu}P_{\mu}+2i\epsilon_{\alpha\beta}Z \text{ with } Z=P_{3} \text{ a central charge; } 0=\{Q_{\alpha}, Q_{\beta}\}=\{\overline{Q}_{\alpha}, \overline{Q}_{\beta}\}.$ 

# §3.3 Spin $\leq 1$ supermultiplets

For 16 supercharges, there is only the vector multiplet.

For 8 supercharges, vector multiplet and (half-)hypermultiplet; fied in [1502.05405, 1502.06594]. in 3d and lower also twisted vector multiplet and twisted hypermultiplet.

5d  $\mathcal{N} = 1$  SCFTs built from 5

For 4 supercharges, vector  $(V = V^{\dagger})$  and chiral  $(\overline{D}_{\dot{\alpha}}X = 0)$  multiplets; in 3d  $\mathcal{N} = 2$  also linear multiplets  $(\epsilon^{\alpha\beta}D_{\alpha}D_{\beta}\Sigma = 0 = \epsilon^{\alpha\beta}\overline{D}_{\alpha}\overline{D}_{\beta}\Sigma)$ ; in 2d  $\mathcal{N} = (2,2)$  also twisted vector, twisted chirals, semichirals, . . .

For 2 supercharges, vector, chiral, linear, Fermi, ...

### §3.4 Other supermultiplets

6d  $\mathcal{N} = (2,0)$  tensor multiplet with self-dual two-form gauge field B (namely  $dB = \star dB$ ), four spinors, five scalars.

6d  $\mathcal{N}=(1,0)$  tensor multiplet (contains one scalar), reduces to 4d  $\mathcal{N}=2$  vector.

6d  $\mathcal{N}=(1,0)$  supergravity multiplet, reduces to 4d  $\mathcal{N}=2$  supergravity multiplet and two vectors.

4d  $\mathcal{N}=1$  supercurrent multiplet contains stress tensor and/or R-symmetry current; is a source for supergravity. Ferrara–Zumino supercurrent  $\overline{D}^{\dot{\alpha}}J_{\alpha\dot{\alpha}}=D_{\alpha}X$  with  $\overline{D}_{\dot{\alpha}}X=0$  contains stress tensor; sources old minimal supergravity. R-symmetry multiplet  $\overline{D}^{\dot{\alpha}}R_{\alpha\dot{\alpha}}=\chi_{\alpha}$ ,  $\overline{D}_{\dot{\alpha}}\chi_{\alpha}=0$ ,  $D^{\alpha}\chi_{\alpha}=\overline{D}_{\dot{\alpha}}\overline{\chi}^{\dot{\alpha}}$  contains (conserved) R-symmetry current; sources new minimal supergravity. Komargodski–Seiberg multiplet [1002.2228]  $\overline{D}^{\dot{\alpha}}S_{\alpha\dot{\alpha}}=\chi_{\alpha}+D_{\alpha}X$ , with  $\chi_{\alpha}$  and X as above, contains both stress tensor and R-symmetry current and sources 16/16 supergravity.

# §4 Supersymmetric (gauge) theories

# §4.1 Maximal super Yang-Mills

Data: gauge group.

**Lorentzian** 10d  $\mathcal{N}=1$  SYM is anomalous unless the gauge group is abelian. Its dimensional reductions are anomaly-free and have one gauge field, 10-d scalars and  $\mathcal{N}$  (symplectic or Majorana, and Weyl or not) spinors. The Lagrangian's R-symmetry Spin(10-d) is contained in the automorphism group of the superalgebra (they coincide for  $d \geq 5$ ).

dim.	$\mathcal N$ spinors	autom. $\supset$ R-sym.
10d	(1,0)  MW	
9d	1 M	
8d	1 M	U(1) = Spin(2)
7d	1 s	USp(2) = Spin(3)
6d	(1,1)  sW	$USp(2)^2 = Spin(4)$
5d	$2 \mathrm{s}$	USp(4) = Spin(5)
4d	$4 \mathrm{M}$	$U(4) \supset Spin(6)$
3d	8 M	$Spin(8) \supset Spin(7)$
2d	(8,8) MW	$\operatorname{Spin}(8)^2 \supset \operatorname{Spin}(8)$
1d	16 M	$Spin(16) \supset Spin(9)$

4d  $\mathcal{N}=4$  has exactly marginal parameter  $\tau=\theta/(2\pi)+4\pi i/g^2$ . Lagrangian theories are characterized by G but non-Lagrangian theories are not ruled out.

3d  $\mathcal{N} = 8$  [0806.1218] Bagger-Lambert, ABJM

# §4.2 Theories with 9 to 12 supercharges

**4d**  $\mathcal{N} = 3$  theories exist, always non-Lagrangian.

**3d**  $\mathcal{N} = 5,6$  [0806.1218, 0807.4924] ABJM, ABJ

## §4.3 Theories with 8 supercharges

**6d**  $\mathcal{N} = (1,0)$  UV-complete Lagrangian gauge theories classified in [1502.05405, 1502.06594].

**5d**  $\mathcal{N}=1$  **SCFTs** built from 5-brane diagrams or UV fixed point of gauge theory. [hep-th/9608111]

 $\mathrm{SU}(2N)$  SYM with  $N_f \leq 7$  fundamental hypermultiplets has  $\mathrm{SO}(2N_f) \times \mathrm{U}(1)_T \subset \mathrm{E}_{N_f+1}$  flavour symmetry enhancement. For  $\mathrm{SU}(2)$  and  $N_f = 0$ , non-trivial " $\theta$ " in  $\pi_4(\mathrm{SU}(2)) = \mathbb{Z}_2$  gives the  $\widetilde{E}_1$  theory with  $\mathrm{U}(1)_T$  symmetry only.

4d  $\mathcal{N}=2$  gauge theories classified in [1309.5160]:  $SU(2)^n$  gauge group with trifundamental hypermultiplets; quiver in the shape of a (possibly single-node) Dynkin or affine Dynkin diagram; finitely many exceptions.

### 4d $\mathcal{N}=2$ generalities

There can be no continuous flavour symmetry enhancement.

The theory on  $\mathbb{R}^4_{\epsilon_1,0}$  (Nekrasov–Shatashvili limit)  $\leftrightarrow$  quantum integrable system with Planck constant  $\epsilon_1$ .

Coulomb moduli  $\leftrightarrow$  action variables.

Supersymmetric vacua  $\leftrightarrow$  eigenstates.

Lift to  $\mathbb{R}^4 \times S^1$  gives K-theoretic Nekrasov partition function. The 5d theory  $\leftrightarrow$  relativistic version of the integrable system.

4d  $\mathcal{N}=2$  (G,G') Argyres–Douglas theories (with G and G' among  $A_k$ ,  $D_k$ ,  $E_{6,7,8}$ ) are engineered as IIB strings on three-fold singularity  $f_G(x_1,x_2)+f_{G'}(x_3,x_4)=0$  where  $f_{A_k}(x,y)=x^2+y^{k+1}$  etc. (see page 2).

3d  $\mathcal{N} = 4$  has  $SU(2)_C \times SU(2)_H$  R-symmetry acting on the Coulomb and Higgs branch. Both branches are hyper-Kähler and the SU(2) rotates their  $\mathbb{CP}^1$  worth of complex structures. Denote  $T \subset G$  the Cartan torus. The Coulomb branch is a holomorphic Lagrangian fibration  $\mathcal{M}_C \to \mathfrak{t}_{\mathbb{C}}/$  Weyl with generic fiber  $T_{\mathbb{C}}^{\vee} \simeq (\mathbb{C}^*)^{\operatorname{rank} G}$ . Its classical  $\operatorname{Hom}(\pi_1(G), \operatorname{U}(1))$ topological flavour symmetry can be enhanced quantum mechanically.

Example: SU(N) (U(N-1)) (U(2)) (U(1)) (edges denote bifundamental hypermultiplets) is the T[SU(N)] theory. Its manifest  $\mathfrak{su}(N) \times \mathfrak{u}(1)^{N-1}$  flavour symmetry enhances to  $\mathfrak{su}(N)^2$ . The T[G] theory has flavour symmetry  $G \times^L G$  acting on Higgs and Coulomb branch respectively. Mirror symmetry exchanges  $G \leftrightarrow {}^LG$ . Gauging G and  ${}^LG$  with two 4d vector multiplets realizes the S-duality domain wall of 4d  $\mathcal{N}=4$  SYM [0804.2902].

2d  $\mathcal{N} = (4,4)$  gauge theories. Typically get in the IR a direct sum of 2d  $\mathcal{N} = (4,4)$  SCFTs (from the Coulomb and Higgs branches) whose central charges are different. Their  $SU(2) \times SU(2)$  left/right-moving R-symmetries are different.

#### **§4.4** Theories with 4 supercharges

Superspace  $\mathbb{R}^{4|4} \ni (x^m | \theta^\alpha, \overline{\theta}^\alpha)$  in  $(2,2) \oplus (2,1) \oplus (1,2)$  of  $\mathfrak{so}(1,3) \text{ or } \mathfrak{so}(4) = \mathfrak{su}(2)^2$ . Supercharges  $Q_{\alpha} = \partial_{\theta^{\alpha}} - i \sigma_{\alpha\dot{\alpha}}^m \overline{\theta}^{\dot{\alpha}} \partial_{x^m}$ and  $\overline{Q}_{\dot{\alpha}} = -\partial_{\overline{\theta}^{\dot{\alpha}}} + i\sigma_{\alpha\dot{\alpha}}^m \theta^{\alpha} \partial_{x^m}$  obey  $\{Q_{\alpha}, \overline{Q}_{\dot{\alpha}}\} = 2i\sigma_{\alpha\dot{\alpha}}^m \partial_{x^m}$ They commute with superderivatives  $D_{\alpha}$  and  $\overline{D}_{\dot{\alpha}}$  obtained by  $\sigma \leftrightarrow -\sigma$ . Note  $\overline{Q}_{\dot{\alpha}} = e^{-A} \overline{D}_{\dot{\alpha}} e^{A}$  for  $A = 2i\theta \sigma^{m} \overline{\theta} \partial_{x^{m}}$ ; likewise  $D_{\alpha}$  is conjugate to  $Q_{\alpha}$ .

4d  $\mathcal{N} = 1$  pure SYM classically has  $U(1)_R$  symmetry, broken by instantons to  $\mathbb{Z}_{2h}$  with  $h = C_2(\text{adj})$ . It confines, is massgapped, and has  $C_2(A)$  vacua associated to breaking  $\mathbb{Z}_{2h}$  to  $\mathbb{Z}_2$  by gaugino condensation  $\langle \lambda \lambda \rangle$ . Witten index  $\text{Tr}(-1)^F = h$ .  $W_{\alpha} = -\frac{1}{4}\overline{D}\overline{D}\mathrm{e}^{-V}D_{\alpha}\mathrm{e}^V$  and  $\overline{W}_{\alpha} = -\frac{1}{4}DD\mathrm{e}^{-V}\overline{D}_{\alpha}\mathrm{e}^V$  field strength.

Wess-Zumino model: chiral multiplet  $\phi$  with superpotential  $W = m\phi^2 + g\phi^3.$ 

**3d** 
$$\mathcal{N} = 2 \text{ [hep-th/9703110]}$$

In Abelian theories or (only approximately) deep in the Coulomb branch, the dual photon  $\gamma$  (a periodic real scalar) is defined by  $d\gamma = J_T = \star F$  where  $J_T$  is the topological current. Chiral superfield  $\Phi = \phi + i\gamma$  where  $\phi$  is the vector multiplet

Field strength 
$$\Sigma = \epsilon^{\alpha\beta} \overline{D}_{\alpha} D_{\beta} V$$
.  
 $Z_{S^3} = \int_{\mathfrak{t}} du \frac{\prod_{\alpha \operatorname{root}} (2 \sinh(\alpha u/2))^2}{\prod_{w \in \mathcal{R}} \cosh(w u/2)} e^{\mathrm{i}k \operatorname{Tr} u^2/(4\pi)}$ 

2d  $\mathcal{N} = (2,2)$ . Classical U(1) × U(1) R-symmetry. The axial U(1) R-symmetry has an anomaly with U(1) gauge symmetry proportional to the total charge under that gauge symmetry.

The gauge field strength is a twisted chiral multiplet  $\Sigma$ .

Integrating out massive chirals gives a twisted superpotential  $-\operatorname{Tr}_R(\Sigma \log(\Sigma/\mu) - \Sigma)$  where  $\Sigma$  combines gauge field strength and twisted masses. FI parameters (twisted superpotentials linear in  $\Sigma$ ) thus run as  $\log(\mu)$  times the sum of charges.

Twisted chiral ring relations:  $\partial W/\partial \Sigma_i \in 2\pi i\mathbb{Z}$ .

1d 
$$\mathcal{N}=4$$

Data: gauge group G, representation V of G for chiral multiplets. Gauge couplings, FI parameters, superpotential W. Flavour Wilson line, twisted and real masses  $v, m_1 + im_2, m_3 \in$  $\mathfrak{g}_F$  that commute.

R-symmetry: SU(2), times U(1) if W has charge 2.

#### $\S4.5$ Theories with 2 supercharges

**3d** N = 1

**2d**  $\mathcal{N} = (0, 2)$ 

**2d**  $\mathcal{N} = (1,1)$ 

1d  $\mathcal{N}=2$ 

Discrete data: gauge group G, chiral multiplets in a representation V of G, Wilson line in a unitary representation  $M = M_0 \oplus M_1$  of  $\mathfrak{g}$ , flavour symmetry group  $G_F \subseteq U(V) \times$  $U(M_0) \times U(M_1)$  commuting with G. Gauge anomaly cancellation:  $M \otimes \det^{1/2} V$  must be a representation of G.

Continuous data: gauge couplings, FI parameters, flavour Wilson line and real mass  $v, \sigma \in \mathfrak{g}_F$  that commute,  $\mathfrak{g}$ -equivariant holomorphic odd map  $Q: V \to \operatorname{End} M$  with  $Q^2 = 0$ describing how supercharges act on M.

Special case: Fermi multiplets in representation  $V_f$  of G with G-equivariant holomorphic maps  $E\colon V\to V_{\mathrm{f}}$  and  $J\colon V\to V_{\mathrm{f}}^\vee$ obeying  $J \cdot E = 0$  are equivalent to Wilson line in M = $\wedge V_{\rm f} \otimes \det^{-1/2} V_{\rm f} \text{ with } Q = E \wedge + J \rfloor.$ 

R-symmetry: U(1) if  $Q: V \to \text{End } M$  has charge 1. Mixing with flavour symmetries not fixed by superconformal algebra.

**NLSM** Chiral multiplet: scalar  $\phi$  in a Kähler target X and fermion in holomorphic bundle  $\phi^*T_X$ . Wilson line depends on a complex of vector bundles  $\mathcal{F}$ . Fermi multiplet takes values in a holomorphic vector bundle  $\mathcal{E}$  with hermitian metric, equivalent to Wilson line with  $\mathcal{F} = \det^{-1/2} \mathcal{E} \otimes \wedge \mathcal{E}$ . Anomaly cancellation:  $\sqrt{K_X} \otimes \wedge T_X \otimes \det^{-1/2} \mathcal{E} \otimes \wedge \mathcal{E} \otimes \mathcal{F}$  is a well-defined vector bundle on X.

#### ξ5 Other theories

Chern-Simons (2m-1)-form  $m \operatorname{Tr} \left( A \int_0^1 \mathrm{d}t (t \mathrm{d}A + t^2 A^2)^{m-1} \right)$ .

#### 2d conformal field theories $\S 5.1$

Virasoro algebra  $Vir_c, c \in \mathbb{R}$ : generators  $L_m, m \in \mathbb{Z}$  obey  $[L_m, L_n] = (m-n)L_{m+n} + \frac{c}{12}(m^3-m)\delta_{m+n,0}$  and  $L_n^{\dagger} = L_{-n}$ .

 $\mathcal{N}=1$  super-Virasoro algebra additionally  $[L_m,G_r]=$  $(m/2-r)G_{m+r}$  and  $\{G_r,G_s\}=2L_{r+s}+\frac{c}{3}(r^2-1/4)\delta_{r+s,0}$ where either  $r \in \mathbb{Z}$  (Ramond algebra) or  $r \in \mathbb{Z} + 1/2$  (Neveu-Schwarz algebra). Adjoint  $G_r^{\dagger} = G_{-r}$ .

 $\mathcal{N}=2$  super-Virasoro algebra  $[L_m,J_n]=-nJ_{m+n},$  $[J_m, J_n] = \frac{c}{3} m \delta_{m+n,0}, [L_m, G_r^{\pm}] = (m/2 - r) G_{m+r}^{\pm},$ 
$$\begin{split} [J_m,G_r^{\pm}] &= \pm G_{m+r}^{\pm}, \; \{G_r^+,G_s^+\} = \{G_r^-,G_s^-\} = 0, \\ \{G_r^+,G_s^-\} &= L_{r+s} + \frac{1}{2}(r-s)J_{r+s} + \frac{c}{6}(r^2 - 1/4)\delta_{r+s,0}. \end{split}$$
Adjoint  $L_m^{\dagger} = L_{-m}, J_m^{\dagger} = J_{-m}, (G_r^{\pm})^{\dagger} = G_{-r}^{\mp}, c^{\dagger} = c$ . The algebras with  $r \in \mathbb{Z}$  (Ramond) or  $r \in \mathbb{Z} + 1/2$  (Neveu–Schwarz) are isomorphic under spectral shift  $\alpha_{\pm 1/2}$  where  $\alpha_{\eta}(L_n)$  $L_n + \eta J_n + \frac{c}{6} \eta^2 \delta_{n,0}, \ \alpha_{\eta}(J_n) = J_n + \frac{c}{3} \eta \delta_n, \ \alpha_{\eta}(G_r^{\pm}) = G_{r \pm \eta}^{\pm}$ Another automorphism is  $G_r^+ \leftrightarrow G_r^-$ ,  $J_m \mapsto -J_m - \frac{c}{3}\delta_{m,0}$ . We get a  $\mathbb{Z} \rtimes \mathbb{Z}_2$  automorphism group.

SW(3/2,2) super-Virasoro algebra has L, G, W, U

bc system

 $\beta \gamma$  system

**Liouville CFT** has  $c = 1 + 6(b + 1/b)^2$  and primary operators with  $h(\alpha) = \alpha(b+1/b-\alpha)$  for "momentum"  $\alpha \in \frac{1}{2}(b+1/b)+i\mathbb{R}$ . **Minimal model**  $\mathcal{M}_{p,q}$  for p > q coprime is a quotient of  $b = i\sqrt{p/q}$  Liouville CFT. It has  $c = 1 - \frac{6(p-q)^2}{pq}$  and primary operators with  $h_{r,s} = \frac{(ps-qr)^2 - (p-q)^2}{4pq}$  for 0 < r < p and 0 < s < q; no degeneracy besides  $h_{r,s} = h_{p-r,q-s}$ . Example: Ising model  $\mathcal{M}_{4,3}$ , tricritical Ising model  $\mathcal{M}_{5,4}$ , Yang-Lee singularity  $\mathcal{M}_{5,2}$ .

Unitary minimal model  $\mathcal{M}_{k+2,k+1}$  is coset  $\frac{\hat{\mathfrak{su}}(2)_{k-1} \times \hat{\mathfrak{su}}(2)_1}{\hat{\mathfrak{su}}(2)_k}$ 

 $\mathcal{N}=2$  minimal models have an ADE classification; the  $A_k$  has c/3=1-2/(k+2) and is the IR limit of a Landau–Ginzburg model with  $W=\Phi^{k+2}$  superpotential.

# §5.2 3d gauge theories

Chern–Simons term  $S_{\text{CS}} = \frac{1}{2\pi} \int_M \mathrm{d}^3 x \operatorname{Tr} \left( A \mathrm{d} A + 2A^3/3 \right) \right)$  for a trivial G-bundle; otherwise realize A as boundary of an  $A_{4d}$  on some 4d manifold X with  $M = \partial X$  and use  $S_{\text{CS}} = \frac{1}{8\pi} \int_X \mathrm{d}^4 x \operatorname{Tr}(F \wedge F)$ . This gives a TQFT (topological quantum field theory).

Magnetic global symmetry  $G_{\text{mag}} = \text{Hom}(\pi_1(G), \text{U}(1))$ . Gauging discrete  $\Gamma \subset G_{\text{mag}}$  enlarges gauge group G to a covering with  $\tilde{G}/\Gamma = G$ . Explicit "topological" current  $J = \star dA/(2\pi)$  for G = U(1).

Contact term in  $\langle JJ \rangle$  where J is a conserved current in 3d:  $\langle J_{\mu}(x)J_{\nu}(y)\rangle = \cdots + \frac{w}{2\pi}\epsilon_{\mu\nu\rho}\partial_{x\rho}\delta^{3}(x-y)$  for some w.

Action of  $SL(2,\mathbb{Z})$  [hep-th/0307041] on 3d CFTs with U(1) flavour symmetry (current J).  $S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$  gauges the U(1) but gives no kinetic energy to A;  $T^k = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix}$  shifts background Chern–Simons level by k, equivalently adds contact term to  $\langle JJ \rangle$ , where  $k \in 2\mathbb{Z}$  if the manifold has no spin structure. Relations:  $S^2 \colon J \to -J$  simply, while  $(ST)^3$  multiplies path integral by theory-indepedent topological invariant of M.

## §5.3 Supergravity and strings

String actions Polyakov action  $L_{\rm P} = \lambda^{mn} [(\partial_m X)(\partial_n X) - g_{mn}] + \frac{1}{\alpha'} \sqrt{-g}$ . Using equations of motion get Nambu–Goto action  $L_{\rm NG} = \frac{1}{\alpha'} \sqrt{-\det[(\partial_m X)(\partial_n X)]}$  or [inspire:109550] action  $L_{\rm BdVHDZ} = \frac{1}{2\alpha'} \sqrt{-g} [g^{mn}(\partial_m X)(\partial_n X) - (d-2)]$  with d=2 the world-sheet dimension.

**Pure supergravities** in  $4 \le d \le 11$ . Gravity is topological in d=3. The maximum number of supercharges Q=32 forbids d>11. A priori, all Q=4k are possible. Focus on 32,16,8,4.

d	Q = 32	16	8	4
11	<b>√</b>			
10	(2,0) (1,1)	$(1,0)^{\ddagger}$		
9	(2, 0) (1, 1) ✓	(1, ∪) ✓		
8	$\checkmark$	$\checkmark$		
7	$\checkmark$	$\checkmark$		
6	(2, 2)	(2,0) (1,1)	(1,0)	
5	$\checkmark$	$\checkmark$	$\checkmark$	
4	N = 8	N = 4	N = 2	N = 1

 $^{\ddagger}$  10d (1,0) supergravity ("type I") has a gravitational anomaly [inspire:192309]. (Perhaps 6d (2,0) or (1,0) supergravity too?)

**M-theory** has as its low-energy limit 11d supergravity, which has two  $\frac{1}{2}$ -BPS membrane solutions (with 16 Killing spinors): M2-brane  $\mathrm{d}s^2 = \Lambda^4\,\mathrm{d}x^2 + \frac{\mathrm{d}y^2}{\Lambda^2}$  with  $\Lambda = (1 + \frac{c_2N_2l^6}{|y|^6})^{-1/6}$ , and M5-brane  $\mathrm{d}s^2 = \Lambda\,\mathrm{d}x^2 + \mathrm{d}y^2/\Lambda^2$  with  $\Lambda = (1 + \frac{c_5N_5l^3}{|y|^3})^{-1/3}$ , where  $x \in \mathbb{R}^{p,1}$  and  $y \in \mathbb{R}^{10-p}$ . In the near horizon  $y \to 0$  these become  $\mathrm{AdS}_4 \times S^7$  and  $\mathrm{AdS}_7 \times S^4$  with 32 Killing spinors.

**Branes** IIA strings: D0, F1 (strings), D2, D4, O4<sup>±</sup>,  $\widetilde{O4}^+$ , NS5, D6, D8 (wall), O8 (wall), etc.. IIB strings: D(-1), F1 (strings), D1, D3, (p,q) 5-branes (includes D5 and NS5), O5<sup>±</sup>,  $\widetilde{O5}^+$ , D7, O7<sup>±</sup>, ON<sup>0</sup>, etc.. M-theory: M2, M5, OM5, M9.

Flat space brane configurations Flat space preserves 32 supercharges. One stack of parallel branes breaks half; two stacks break all unless:  $\mathrm{D}p$  and  $\mathrm{D}q$  have 0, 4 or 8 directions that one brane spans and not the other;  $\mathrm{D}p$  branes have 1 or 3 directions transverse to any NS5; any pair of NS5 branes has 2, 4, 6 common directions. Kappa-projection: for  $\mathrm{D}p$  is  $\Gamma_{01...p}\epsilon_L=\epsilon_R$ , for NS5 is  $\Gamma_{01...5}\epsilon_L=\epsilon_L$ . Then at least  $32/2^{\#\mathrm{stacks}}$  supercharges preserved.

**S-rule, brane creation** Let a  $\mathrm{D}p$  have 3 directions transverse to an NS5. Zero or one  $\mathrm{D}(p-2)$  can stretch between the two (spanning common directions and directions where neither  $\mathrm{D}p$  nor NS5 stretch). Moving  $\mathrm{D}p$  through NS5 toggles between zero and one.

**Little string theory (LST)** Decoupled  $g_s \to 0$ , fixed  $\alpha$  description of k coincident NS5 branes on transverse  $T^5$  gives (1,1) LST for IIB and (2,0) LST for IIA. Has AdS/CFT dual with linear dilaton background.

# §5.4 Integrable models

Sine-Gordon model in 2d:  $\mathcal{L} = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi + m^2 (\cos \phi - 1)$  has eom  $\Box \phi + m^2 \sin \phi = 0$ .

Relativistic quantum Toda chain.  $H = \sum_{n=1}^{N} (\cos(2\eta \hat{p}_n) + g^2 \cos(\eta \hat{p}_n + \eta \hat{p}_{n+1}) e^{x_{n+1} - x_n})$ . Its non-relativistic limit is  $\eta \to 0$  imaginary with  $g/(i\eta\sqrt{2}) = c$  fixed.

# §6 Dualities

# §6.1 4d $\mathcal{N} = 1$ dualities

**IR** duality: the "electric" theory A has the same IR limit as the "magnetic" theory B: TQFT, SCFT, free theory, infinite flow, or sum of products thereof.

Gauge-invariant chirals  $\mathcal{O}$  of trial R-charge  $\leq 2/3$  are free and of true IR R-charge 2/3 thanks to mixing with accidental  $\mathfrak{u}(1)$  acting on  $\mathcal{O}$ . Other view: given a term  $\delta W$ , trial R-charge obeys  $R(\delta W)=2$  but true R-charge maybe  $R(\delta W)>2$ ; then  $\delta W$  is irrelevant and leaves some chiral free.

Typical evidence: global symmetries, 't Hooft anomaly matching, moduli space of vacua, chiral rings, behaviour of these under F-term deformations, superconformal index  $(S_b^3 \times S^1 \text{ partition function})$ .

Seiberg duality [hep-th/9411149]  $\overline{SU(F)}$   $\overline{Q}$   $\overline{SU(C)}$   $\overline{Q}$   $\overline{SU(F)}$  dual to  $\overline{SU(F)}$   $\overline{Q}$   $\overline{SU(C')}$   $\overline{Q}$   $\overline{SU(F)}$  with  $W = \text{Tr}(M\tilde{q}q)$  and  $C' = F - C \ge 0$  (here  $SU(1) = SU(0) = \{1\}$ ).

Non-anomalous global symmetries  $\mathfrak{su}(F)^2 \times \mathfrak{u}(1)_B \times \mathfrak{u}(1)_R$  coincide, where  $(Q, \tilde{Q}), M, (\tilde{q}, q)$  have  $\mathfrak{u}(1)_B$  charges  $\pm \frac{1}{C}, 0, \pm \frac{1}{F-C}$  and trial  $\mathfrak{u}(1)_R$  charges  $\frac{F-C}{F}, 2\frac{F-C}{F}, \frac{C}{F}$ .

- For  $0 \le C \le F/3$  the SU(C) theory is IR-free.
- For F/3 < C < 2F/3 flow to SCFT.
- For  $2F/3 \le C \le F$  the SU(C') theory is IR-free.
- For 0 < F < C supersymmetry is broken.

Gauge-invariants match: mesons  $M^{j}_{i} = \tilde{Q}^{j}Q_{i}$ ; (anti)barvons  $B_{\mathcal{A}} = \bigwedge_{i \in \mathcal{A}} Q_i \leftrightarrow \bigwedge_{i \notin \mathcal{A}} \tilde{q}^i$  and  $B_{\mathcal{A}} = \bigwedge_{j \in \mathcal{A}} Q^j \leftrightarrow \bigwedge_{j \notin \mathcal{A}} q_j$  for  $\mathcal{A} \subset [1, F]$  with  $|\mathcal{A}| = C$ . Relation  $\tilde{B}_{\mathcal{A}'}B_{\mathcal{A}} = \det(M^j{}_i)_{i \in \mathcal{A}}^{j \in \mathcal{A}'}$  of SU(C) theory only holds quantumly in SU(C') theory.

A mass term  $W = m\tilde{Q}_F Q_F$  decouples a flavour  $(F \to F - 1)$ and Higgses SU(C') to SU(C'-1). Dually, Higgsing SU(C)to SU(C-1) using  $\langle Q_F Q_F \rangle \to \infty$  (so  $F \to F-1$ ) gives mass to  $q_F$ ,  $\tilde{q}_F$  and leaves SU(C') fixed.

**SO:**  $\overline{SU(F)} \stackrel{Q}{\rightleftharpoons} (\overline{SO(C)})$  dual to  $M(\overline{SU(F)}) \stackrel{q}{\rightleftharpoons} (\overline{SO(C')})$  with C' = F - C + 4 and W = Mqq (we assume  $C, C' \ge 4$ ).

Non-anomalous global symm.  $\mathfrak{u}(1)_R \times (\mathrm{SU}(F) \times \mathbb{Z}_{2F})/\mathbb{Z}_{F,\mathrm{diag}};$   $Q,\,M,\,q$  have trial  $\mathfrak{u}(1)_R$  charges  $\frac{F-C+2}{F},\,2\frac{F-C+2}{F},\,\frac{C-2}{F}$  and are  $\overline{\square}$ , sym<sup>2</sup>  $\overline{\square}$ ,  $\square$  under SU(F), while  $\mathbb{Z}_{2F}$  acts by  $Q \to e^{\pi i/F}Q$ ,  $q \to \mathcal{C}e^{-\pi i/F}q$  with  $\mathcal{C}$  charge conjugation.

- For F/3 < C 2 < 2F/3 flow to SCFT.
- For  $2F/3 \le C 2 \le F 2$  the SU(C') theory is IR-free.
- For  $F + 5 \le C$  supersymmetry is broken.

Gauge-invariants match: mesons  $M_{(ij)} = Q_i Q_j$ ; field strength  $W_{\mathcal{A},\alpha} = W_{\alpha} \wedge \bigwedge_{i \in \mathcal{A}} Q_i \leftrightarrow W_{\alpha} \wedge \bigwedge_{i \notin \mathcal{A}} q^i \text{ for } |\mathcal{A}| = C - 2 \text{ flavours};$ baryons  $B_{\mathcal{A}} = \bigwedge_{i \in \mathcal{A}} Q_i \leftrightarrow W_{\alpha} \wedge W_{\alpha} \wedge \bigwedge_{i \notin \mathcal{A}} q^i$  for  $|\mathcal{A}| = C$ and  $b_{\mathcal{A}} = W_{\alpha} \wedge W_{\alpha} \wedge \bigwedge_{i \in \mathcal{A}} Q_i \leftrightarrow \bigwedge_{i \notin \mathcal{A}} q^i$  for  $|\mathcal{A}| = C - 4$ .

USp:  $?(2F) \xrightarrow{Q} (\text{USp}(2C))$  dual to  $M \stackrel{?}{} ?(2F) \xrightarrow{\tilde{q}} (\text{USp}(2C'))$ with W = and C' = F - C - 2.

**Self-duality** in the SU, SO, USp dualities for F = 2C, 2C -4,2C+2 respectively, namely  $C(R_{\text{chirals}})=2C(\text{adj})$ ; adding an adjoint gives  $\mathcal{N} = 2$  SCFTs.

Kutasov–Schwimmer–Seiberg duality [hep-th/9510222]

$$\begin{array}{c|c} SU(F) & X & \tilde{Q} \\ \hline SU(F) & SU(C) & SU(F) \\ \hline \end{array} \text{ dual to } \begin{array}{c|c} SU(F) & \tilde{q} & \tilde{SU(C')} & q \\ \hline M_1, \dots, M_k & & \\ \hline \end{array}$$

for  $W_{\text{el}} = \text{Tr } P(X) = \sum_{j=1}^{k+1} s_{k+1-j} \text{Tr } X^j/j \text{ (with } s_1 = 0)$  and  $W_{\text{mag}} = \alpha(s) - \text{Tr } P(x) + \frac{1}{\mu^2} \sum_{1 \le i \le j \le k} s_{k-j} M_i \tilde{q} x^{j-i} q$ , for some function  $\alpha$  and mass  $\mu$ . Here,  $C' = kF - C \ge 0$ .

Non-anomalous global symmetries  $\mathfrak{su}(F)^2 \times \mathfrak{u}(1)_B \times \mathfrak{u}(1)_B$ where  $(Q, \tilde{Q}), X, (q, \tilde{q}), x$  have  $\mathfrak{u}(1)_B$  charges  $\pm \frac{1}{C}, 0, \pm \frac{1}{C'}, 0$  and  $\mathfrak{u}(1)_R$  charges  $1 - \frac{2C}{(k+1)F}, \frac{2}{k+1}, 1 - \frac{2C'}{(k+1)F}, \frac{2}{k+1}$ .

Gauge-invariants: mesons  $M_i = \tilde{Q}X^{j-1}Q$ ; baryons  $B_A =$  $\bigwedge_{(i,j)\in\mathcal{A}}(X^{j-1}Q_i)\leftrightarrow \bigwedge_{(i,j)\notin\mathcal{A}}(x^{j-1}q_i)$  and antibaryons  $\tilde{B}_{\mathcal{A}}=$  $\textstyle \bigwedge_{(i,j)\in\mathcal{A}}(\tilde{Q}_iX^{j-1}) \leftrightarrow \bigwedge_{(i,j)\not\in\mathcal{A}}(\tilde{q}_ix^{j-1}) \text{ for } \mathcal{A}\subset \llbracket 1,F\rrbracket \times \llbracket 1,k\rrbracket$ with  $|\mathcal{A}| = C$ ; and  $\operatorname{Tr} X^j/j = \partial W/\partial s_{k+1-j} = \partial W_{\text{mag}}/\partial s_{k+1-j}$ expressed in terms of Tr  $x^i$  (for this,  $\alpha(s)$  matters); ...

Aharony-Sonnenschein-Yankielowicz [hep-th/9504113] SU(C) with F flavours  $(Q, \tilde{Q})$ , F' flavours  $(Z, \tilde{Z})$  and an adjoint X, with  $W_{\rm el} = \tilde{Z}XZ + {\rm Tr} X^3/3$  is dual to  ${\rm SU}(2F + F' - C)$ with F + F' flavours  $q, \tilde{q}, z, \tilde{z}$ , an adjoint x, gauge singlets  $M_i$ ,  $N, \tilde{N} \text{ and } W_{\text{mag}} = \tilde{z}xz + \text{Tr } x^3/3 + M_1\tilde{q}xq + M_2\tilde{q}q + N\tilde{z}q + \tilde{N}\tilde{q}z$ Duality likely generalizes to  $W = \operatorname{Tr} P(X) + \sum_{i} \tilde{Z}_{i} X^{k_{i}} Z_{i}$  with an SU $(F \deg P + \sum_{i} k_i - C)$  dual.

Other 4d  $\mathcal{N} = 1$  dualities Brodie, Intriligator-Pouliot, Argyres-Intriligator-Leigh-Strassler, Klebanov cascade, Intriligator-Leigh-Strassler, Kutasov-Lin.

#### 3d dualities $\S6.2$

We recall Sp(n) = USp(2n).

Level-rank duality of Chern-Simons TQFTs (proven). For  $k, N \geq 0$ , have  $U(k)_{\pm N} \leftrightarrow SU(N)_{\mp k}$ ,  $SO(k)_{\pm N} \leftrightarrow SO(N)_{\mp k}$ ,  $\operatorname{Sp}(k)_{\pm N} \leftrightarrow \operatorname{Sp}(N)_{\mp k}$  but subtleties [1607.07457].

Chern–Simons matter dualities [1706.08755] where scalars and fermions are in  $\mathbb{C}^N$  for U(N),  $\mathbb{R}^N$  for SO(N),  $?^{2N}$  for Sp(N), and scalars have quartic coupling. Assuming N, k, F,  $\pm$  obey  $N \in \mathbb{Z}_{\geq 0}$ ,  $F/2 \pm k \in \mathbb{Z}_{\geq 0}$  and an unknown upper bound  $F < N_*$  greater than 2|k|, conjectured dualities (modified for SO(1) and SO(2), see reference):

- $SU(N)_k \& F$  fermions  $\leftrightarrow U(F/2 \pm k)_{\mp N} \& F$  scalars;
- $SO(N)_k$  & F fermions  $\leftrightarrow SO(F/2 \pm k)_{\mp N}$  & F scalars;
- $\operatorname{Sp}(N)_k \& F \text{ fermions} \leftrightarrow \operatorname{Sp}(F/2 \pm k)_{\mp N} \& F \text{ scalars}.$

Denote X = SU, SO, Sp and X' = U, SO, Sp to uniformize cases. Turn on equal mass m for all fermions. For  $\mp m \gg g^2$ the theory flows to  $X(N)_{k\mp F/2} \leftrightarrow X'(|k\mp F/2|)_{-\operatorname{sign}(k\mp F/2)N}$ . If  $F \leq 2|k|$  the (only) bosonic dual has the same two phases. If  $2|k| < F < N_*$  a confining phase sits between these phases; each bosonic dual describes two of the three phases. In the confining phase the global symmetry breaks to  $Y(F/2+k) \times$  $Y(F/2-k) \subset Y(F)$ , giving an NLSM on the quotient and N times the Wess–Zumino term. Here Y is Sp for SU(2) and otherwise X.

Integrating out one fermion of large mass m shifts  $F \to F-1$ . For  $\mp m > 0$  get  $k \to k + 1/2$ ; the dual scalar becomes massive and k + F/2 is unchanged. For  $\pm m > 0$  get  $k \to k - 1/2$ ; the dual scalar has Mexican potential so  $k + F/2 \rightarrow k + F/2 - 1$ .

With scalars and fermions [1712.00020, 1712.04933] (less firm footing). Denote " $\phi$ " and " $\psi$ " for scalars and fermions, let (X, X') be one of (SU, U), (SO, SO), (Sp, Sp), and assume  $0 \le S \le N$ ,  $0 \le F \le k$  and additionally  $(S, F) \ne (N, k)$  for (X, X') = (SU, U) and  $S + F + 3 \le N + k$  for SO. The duality is then  $X(N)_{k-F/2}$ ,  $S\phi$ ,  $F\psi \leftrightarrow X'(k)_{-N+S/2}$ ,  $F\phi$ ,  $S\psi$ .

#### Field theory dualities $\S6.3$

2d  $\mathcal{N} = (0, 2)$  Gadde-Gukov-Putrov triality (IR).

2d  $\mathcal{N} = (2, 2)$  mirror symmetry of Calabi-Yau sigma models (exact).

2d  $\mathcal{N} = (2,2)$  Hori-Tong (SU), Hori (Sp. SO groups), plus adjoint (ADE-type and  $(2,2)^*$ -like) dualities (IR).

2d  $\mathcal{N} = (2, 2)$  Hori-Vafa/Hori-Kapustin duality of gauged linear sigma models and Landau–Ginzburg models (IR).

3d Chern-Simons level-rank duality.

3d  $\mathcal{N}=2$  Aharony, Giveon-Kutasov, Aharony-Fleischer dualities (IR).

3d  $\mathcal{N}=2$  and  $\mathcal{N}=4$  mirror symmetry exchanging Coulomb and Higgs branches (IR).

S-duality of 4d  $\mathcal{N} = 2$  gauge theories (exact).

S-duality of 4d  $\mathcal{N} = 4$  SYM (exact).

#### §6.4 String theory dualities

In this table "type IIA" etc. refer to string theories not supergravities

F-theory on K3	$\Leftrightarrow E_8 \times E_8$ heterotic on $T^2$
M-theory on K3	$\Leftrightarrow$ heterotic or type I on $T^3$
Type IIA on K3	$\Leftrightarrow$ heterotic or type I on $T^4$
	$\Leftrightarrow$ heterotic or type I on CY <sub>3</sub>
M-theory on $K3^2$	$\Leftrightarrow$ type IIA on $T^3/\mathbb{Z}_2$

# §7 Manifolds

# §7.1 Pseudo-Riemannian geometry

 $\begin{array}{l} T_{\ldots\lambda[\mu_1\ldots\mu_m]\nu\ldots}=m!^{-1}\sum_{\sigma\in S_m}\epsilon(\sigma)T_{\ldots\lambda\mu_{\sigma(1)}\ldots\mu_{\sigma(m)}\nu\ldots} \text{ antisymmetrization, where }\epsilon(\sigma)=\pm 1 \text{ is the signature of the permutation; symmetrization }T_{\ldots\lambda(\mu_1\ldots\mu_m)\nu\ldots} \text{ is without }\epsilon. \end{array}$  Derivatives:  $\begin{array}{l} \partial_\mu=\partial/\partial x^\mu \text{ and } T^{\nu_1\ldots\nu_n}_{\rho_1\ldots\rho_r,\,\mu_1\ldots\mu_m}=\partial_{\mu_1}\cdots\partial_{\mu_m}T^{\nu_1\ldots\nu_n}_{\rho_1\ldots\rho_r} \\ \text{ and } T^{\nu_1\ldots\nu_n}_{\rho_1\ldots\rho_r;\,\mu_1\ldots\mu_m}=\nabla_{\mu_1}\cdots\nabla_{\mu_m}T^{\nu_1\ldots\nu_n}_{\rho_1\ldots\rho_r} \text{ (namely ";" is $\nabla$)}. \end{array}$ 

Connection  $\nabla = \partial + \Gamma$  in terms of Christoffel symbols  $\Gamma$ .  $T^{\nu_1...}_{\rho_1...;\mu} = T^{\nu_1...}_{\rho_1...;\mu} + (T^{\lambda\nu_2...}_{\rho_1...}\Gamma^{\nu_1}_{\lambda\mu} + \cdots) - (T^{\nu_1...}_{\lambda\rho_2...}\Gamma^{\lambda}_{\rho_1\mu} + \cdots)$  for a tensor. In particular,  $\nabla_{\mu}v^{\nu} = \partial_{\mu}v^{\nu} + v^{\lambda}\Gamma^{\nu}_{\lambda\mu}$  for a vector and  $\nabla_{\mu}\omega_{\nu} = \partial_{\mu}\omega_{\nu} - \omega_{\lambda}\Gamma^{\lambda}_{\nu\mu}$  for a one-form. Extra  $-w(\log\Omega)_{,\mu}T^{\nu_1...}_{\rho_1...}$  for a weight w tensor density, where  $\Omega$  is the volume factor ( $|\det g|^{1/2}$  for a metric).

The Levi-Civita connection of a metric g is  $\nabla = \partial + \Gamma$  with  $\Gamma^{\lambda}{}_{\nu\rho} = \frac{1}{2} g^{\lambda\mu} (\partial_{\rho} g_{\mu\nu} + \partial_{\nu} g_{\mu\rho} - \partial_{\mu} g_{\nu\rho})$ . It is the only torsion-free connection  $(\Gamma^{\lambda}{}_{[\mu\nu]} = 0)$  that kills the metric. Note that  $\Gamma^{\lambda}{}_{\lambda\rho} = \frac{1}{2} g^{\lambda\mu} \partial_{\rho} g_{\lambda\mu} = \frac{1}{2} \partial_{\rho} \log|\det g|$ . Denote  $\sqrt{g} = |\det g|^{1/2}$ . Then  $\sqrt{g} \nabla_{\nu} v^{\nu} = \partial_{\nu} (v^{\nu} \sqrt{g})$  and  $\sqrt{g} \nabla_{\nu} F^{[\nu\rho]} = \partial_{\nu} (F^{[\nu\rho]} \sqrt{g})$  are total derivatives.

Killing vector  $k_{\mu}$  such that  $\nabla_{(\mu}k_{\nu)}=0$ . For a symmetric conserved stress-tensor T we have  $\nabla_{\mu}(k_{\nu}T^{\mu\nu})=0$ , giving conserved quantities.

# §7.2 G-structures, holonomy

**Structure group.** A G-structure on a manifold X (with  $n = \dim_{\mathbb{R}} X$ ) is a G-subbundle of the  $\mathrm{GL}(n,\mathbb{R})$ -principal bundle  $\mathrm{GL}(TX)$  of tangent frames, namely a global section of  $\mathrm{GL}(TX)/G$ .

A  $\mathrm{GL}_+(n,\mathbb{R})=\{\det>0\}$  structure on X is equivalent to an orientation. A  $\mathrm{SL}(n,\mathbb{R})$  structure is equivalent to a volume form. Similar definitions for Riemannian manifolds etc.:

G-structure Manifold type	Other characterization $^{\ddagger}$
O(n) Riemannian	metric $g > 0$
SO(n) oriented, Riemannian	
O(p,q) pseudo-Riemannian	metric of signature $(p,q)$
$SO_{+}(p,q)$ pseudo-Riemannian, c	oriented, time-oriented
Pin <sub>±</sub> or Spin (pseudo)-Riemanni	
$\overline{\mathrm{GL}(n/2,\mathbb{C})}$ Almost complex	$\mathbb{C} \subset TX \text{ (i.e., } J^2 = -1)$
$\operatorname{Sp}(2n/2,\mathbb{R})$ Almost symplectic	Non-degenerate $\omega \in \Omega^2 X$
U(n/2) Almost Hermitian	Two compatible $(g, J, \omega)^{\S}$
$U^*(n/2)$ Almost hypercomp	$\overline{\text{lex}^{\P}}$ $J_1, J_2, J_3 \subset TX$
USp(n/2) Almost hyperHerm	itian $(g, J_{1,2,3}, \omega_{1,2,3})$
$U^*(n/2)USp(2)$ Almost quatern	ionic <sup>¶</sup> $\mathbb{H} \subset TX$
USp(n/2)USp(2) Almost quatern	ion-Hermitian $(g, \mathbb{H}, \omega_{1,2,3})$

<sup>&</sup>lt;sup>‡</sup> All sections are global. For instance, an almost complex structure is a global section J of End TX with  $J^2 = -1$ . A metric is a global section g of  $S^2(T^*X)$ .

On an almost complex manifold, (p,q)-forms are wedge products  $\Omega^{(p,q)}X = \bigwedge^p (\Omega^{(1,0)}X) \wedge \bigwedge^q (\Omega^{(0,1)}X)$  where J acts by  $\pm i$  on  $\Omega^1X = \Omega^{(1,0)}X \oplus \Omega^{(0,1)}X$ . The exterior derivative is

 $d = d^{2,-1} + d^{1,0} + d^{0,1} + d^{-1,2}$  with  $d^{i,j} : \Omega^{(p,q)} \to \Omega^{(p+i,q+j)}$ . Dolbeault differential operators are  $\partial = d^{1,0}$  and  $\overline{\partial} = d^{0,1}$ .

An almost symplectic 2m-manifold admits the volume form  $\omega^m/m!$ . On an almost Hermitian manifold X it is equal to the Riemannian volume form and belongs to  $\Omega^{(m,m)}X$ .

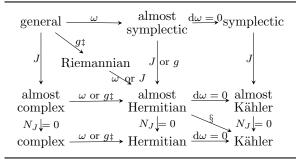

¶ While almost quaternionic manifolds have a 3d subbundle of End TX locally spanned by  $J_1, J_2, J_3$  with  $J_i^2 = J_1 J_2 J_3 = -1$ , almost hypercomplex manifolds require  $J_1, J_2, J_3$  to be global.

**Integrability.** A G-structure is k-integrable (resp. integrable) near  $x \in X$  if it can be trivialized to order k (resp. all orders) in a neighborhood of x. We automatically have 0-integrability.

Any Riemannian structure is 1-integrable thanks to Riemann normal coordinates. Integrability is equivalent to the Riemann curvature vanishing.

An almost complex structure is complex if (equivalently) it is integrable; it is 1-integrable; it has a vanishing Nijenhuis tensor  $N_J: \bigwedge^2 X \to TX$  defined on vector fields u, v by the Lie brackets  $N_J(u, v) = -J^2[u, v] + J[Ju, v] + J[u, Jv] - [Ju, Jv]$ ; the Lie bracket of (1,0) vector fields is a (1,0) vector field;  $d = \partial + \overline{\partial}$  namely  $d^{2,-1} = 0 = d^{-1,2}$ ; or  $\overline{\partial}^2 = 0$ .

A symplectic structure is an integrable almost symplectic structure. Equivalently, it is 1-integrable:  $d\omega = 0$ . Altogether,

(Almost) quaternionic/quaternion Hermitian/quaternion Kähler and (almost) hypercomplex/hyper<br/>Hermitian/hyper Kähler manifolds are defined by replacing<br/> J by a 3d subbundle of End TX or by global sections<br/>  $J_1,J_2,J_3$  as in the table of G-structures.<br/>  $^\ddagger$  Since  $\mathrm{GL}(n,\mathbb{R})/\mathrm{O}(n)$  is contractible, any manifold admits (non-canonically) an  $\mathrm{O}(n)$ -structure, namely a smooth choice of which frames are orthonormal, i.e., a Riemannian metric g.<br/> Similarly  $\mathrm{GL}(n/2,\mathbb{C})/\mathrm{U}(n/2)$  is contractible so almost complex manifolds admit almost Hermitian structures.

§ An almost Hermitian manifold is Kähler if (equivalently) its U(n/2)-structure is 1-integrable;  $d\omega = 0$  and  $N_J = 0$ ;  $\nabla \omega = 0$ ;  $\nabla J = 0$ ; or the holonomy group is in U(n/2). Locally,  $\omega = i\partial \bar{\partial} \rho$  for some real-valued Kähler potentials  $\rho$ , and  $\omega$  is invariant under Kähler transformations  $\rho \to \rho + f(z) + \bar{f}(\bar{z})$ .

The holonomy group at  $x \in X$  of a connection  $\nabla$  on a bundle  $E \to X$  is the group of symmetries of  $E_x$  arising from parallel transport along closed curves based at x.

For Riemannian manifolds X the holonomy group is defined as that of the Levi-Civita connection on the tangent bundle. It is a subgroup of  $\mathrm{O}(n)$  (or  $\mathrm{SO}(n)$  for X orientable) since parallel transport preserves orthogonality  $(\nabla g = 0)$ .

If the holonomy group acts reducibly on the tangent space then X is locally (globally if X is geodesically complete) a product. Simply connected X that are locally neither products nor symmetric spaces (we give a list later) can have the following special holonomy subgroups of SO(n) (Berger's theorem)

<sup>§</sup> Any two of  $(g,J,\omega)$  fix the third by  $\omega_{ik}=J_i{}^jg_{jk}$  if they are compatible:  $J_i{}^{\bar{\jmath}}J_l{}^k\omega_{jk}=\omega_{il}$  or  $J_i{}^{\bar{\jmath}}J_l{}^kg_{jk}=g_{il}$  namely  $\omega$  or g is J-invariant, or  $\omega_{ij}g^{jk}\omega_{kl}=-g_{il}$ . In a basis  $e^{\beta},\bar{e}^{\bar{\gamma}}$  (=  $\mathrm{d}z^{\beta},\mathrm{d}\bar{z}^{\bar{\gamma}}$  for Hermitian manifolds) of (1,0) and (0,1) forms,  $\omega=\frac{i}{2}h_{\beta\bar{\gamma}}\,e^{\beta}\wedge\bar{e}^{\bar{\gamma}}$  and  $g=\frac{1}{2}h_{\beta\bar{\gamma}}(e^{\beta}\otimes\bar{e}^{\bar{\gamma}}+\bar{e}^{\bar{\gamma}}\otimes e^{\beta})$ .

Holonomy	Manifold type	$\dim_{\mathbb{R}}$
U(m) SU(m)	Kähler Calabi–Yau $\mathrm{CY}_m$	2m $2m$
$(\operatorname{USp}(2k) \times \operatorname{USp}(2))/\mathbb{Z}_2$ $\operatorname{USp}(2k)$	quaternionic Kähler hyperKähler	$4k \\ 4k$
$\begin{array}{c} \operatorname{Spin}(7) \\ \operatorname{G}_2 \end{array}$	$Spin(7)$ manifold $G_2$ manifold	8 7

Note that hyperKähler  $\implies$  Calabi–Yau  $\implies$  Kähler since  $\mathrm{USp}(m)\subset\mathrm{SU}(m)\subset\mathrm{U}(m)$ . In contrast, quaternionic-Kähler manifolds are not Kähler.

A Calabi–Yau manifold is a Kähler manifold such that (equivalently) some Kähler metric has global holonomy group in SU(m); the structure group can be reduced to SU(m); or the holomorphic canonical bundle is trivial i.e., there exists a nowhere vanishing holomorphic top-form.

For simply connected manifolds, the conditions above are equivalent to the following (always equivalent) conditions on X: some Kähler metric has local holonomy group in SU(m); some Kähler metric has vanishing Ricci curvature; the first real Chern class vanishes; a positive power of the holomorphic canonical bundle is trivial; X has a finite cover with trivial holomorphic canonical bundle; X has a finite cover equal to the product of a torus and a simply connected manifold with trivial holomorphic canonical bundle.

### Spin structures

## Symmetric spaces

**K3** surfaces are the only  $CY_2$ : they have holonomy SU(2).

**Yau's theorem.** Fix a complex structure on a compact complex manifold X of  $\dim_{\mathbb{C}} X > 1$  and vanishing real first Chern class. Any real class  $H^{1,1}(X,\mathbb{C})$  of positive norm contains a unique Kähler form whose metric is Ricci flat.

(from Wikipedia on Calabi conjecture: "The Calabi conjecture states that a compact Khler manifold has a unique Khler metric in the same class whose Ricci form is any given 2-form representing the first Chern class.")

## §8 Misc

### §8.1 Special functions

Multiple gamma function. For  $a_i \in \mathbb{C}$  with  $\operatorname{Re} a_i > 0$ ,  $\Gamma_N(x|\vec{a}) = \prod_{\vec{n}}^{\operatorname{reg.}} (x + \vec{n} \cdot \vec{a})^{-1} = \exp(\partial_s \sum_{\vec{n}} (x + \vec{n} \cdot \vec{a})^{-s}|_{s=0})$ , where  $\vec{n} \in \mathbb{Z}_{\geq 0}^N$ . Here, we zeta-regularized the product; the sum is analytically continued from  $\operatorname{Re} s > N$ . The meromorphic  $x \mapsto \Gamma_N(x|\vec{a})$  has no zero and poles at  $x = -\vec{n} \cdot \vec{a}$  (simple poles for generic  $\vec{a}$ ).  $\Gamma_0(x|) = 1/x$ ,  $\Gamma_1(x|a) = a^{x/a-1/2}\Gamma(x/a)/\sqrt{2\pi}$ ,  $\Gamma_N(x|\vec{a}) = \Gamma_{N-1}(x|a_1,\ldots,a_{N-1})\Gamma_N(x+a_N|\vec{a})$  and it is invariant under permutations of  $\vec{a}$ .

**Plethystic exponential.** Let  $\mathbf{m} \subset R[[x_1,\ldots,x_n]]$  be series with no constant term over a ring R. Then plexp:  $\mathbf{m} \to 1+\mathbf{m}$  obeys  $\operatorname{plexp}[x_i^p] = 1/(1-x_i^p)$ ,  $\operatorname{plexp}[f+g] = \operatorname{plexp}[f]\operatorname{plexp}[g]$  and  $\operatorname{plexp}[\lambda f] = \operatorname{plexp}[f]^{\lambda}$  for  $\lambda \in R$ . It maps an index of single-particle states f(x) to that of multiparticle states  $\operatorname{plexp} f(x) = \exp \sum_{k>1} \frac{1}{k} f(x_1^k,\ldots,x_n^k)$ .

**q-Pochhammer**  $(a;q)_{\infty}=\operatorname{plexp} \frac{-a}{1-q}=\prod_{k=0}^{\infty}(1-aq^k)$  and finite version  $(a;q)_n=(a;q)_{\infty}/(aq^n;q)_{\infty}$ . Products are often denoted  $(a_1,\ldots,a_N;q)_n=(a_1;q)_n\cdots(a_N;q)_n$ . Properties:  $(a;q)_{-n}(q/a;q)_n=(-q/a)^nq^{n(n-1)/2}$  and q-binomial theorem  $(ax;q)_{\infty}/(x;q)_{\infty}=\sum_{n=0}^{\infty}x^n(a;q)_n/(q;q)_n$ .

**q-gamma (or basic gamma) function** for |q| < 1,  $\Gamma_q(x) = (1-q)^{1-x}(q;q)_{\infty}/(q^x;q)_{\infty}$  obeys  $\Gamma_q(x+1) = \frac{1-q^x}{1-q}\Gamma_q(x)$  and  $\Gamma_q(x) \xrightarrow{q\to 1} \Gamma(x)$ . It has simple poles at  $x \in \mathbb{Z}_{\leq 0}$  and no zero. **Modular form** of weight k: holomorphic on  $\mathbf{H} = \{\operatorname{Im} \tau > 0\}$  and as  $\tau \to i\infty$  and obeys  $f(\frac{a\tau+b}{c\tau+d}) = (c\tau+d)^k f(\tau)$ .

**Dedekind eta function:**  $\eta(\tau) = q^{1/24}(q;q)_{\infty}$  for  $q = e^{2\pi i \tau}$ .  $\Delta = \eta^{24}$  is a modular form of weight 12.

Theta functions: q-theta  $\theta(z;q) = (z;q)_{\infty}(q/z;q)_{\infty}$  obeys  $\theta(z;q) = \theta(q/z;q) = -z\theta(1/z;q)$ . Variant  $\theta_1(z;q) = \theta_1(\tau|u) = iz^{-1/2}q^{1/12}\eta(\tau)\theta(z;q) = -iz^{1/2}q^{1/8}(q;q)_{\infty}(qz;q)_{\infty}(1/z;q)_{\infty}$  with  $z = e^{2\pi iu}$ .

Eisenstein series  $(k \ge 1)$   $E_{2k} = 1 + \frac{2}{\zeta(1-2k)} \sum_{n=1}^{\infty} n^{2k-1} \frac{q^n}{1-q^n}$  obeys  $E_{2k}(\frac{a\tau+b}{c\tau+d}) = (c\tau+d)^{2k} E_{2k}(\tau) + \frac{6}{\pi \mathrm{i}} c(c\tau+d) \delta_{k=1}$ . For  $k \ge 2$  it is a modular form and  $E_{2k} = \frac{1}{2\zeta(2k)} \sum_{0 \ne \lambda \in \mathbb{Z} + \tau \mathbb{Z}} \lambda^{-2k}$ .

Elliptic gamma function  $\Gamma(z;p,q)=\operatorname{plexp} \frac{z-pq/z}{(1-p)(1-q)}=\prod_{m=0}^{\infty}\prod_{n=0}^{\infty}(1-p^{m+1}q^{m+1}z^{-1})/(1-p^mq^nz)$  obeys  $\Gamma(z;p,q)=\Gamma(z;q,p)=1/\Gamma(pq/z;p,q)$  and  $\Gamma(pz;p,q)=\theta(z;q)\Gamma(z;p,q)$  and  $\Gamma(z;0,q)=1/(z;q)_{\infty}$ .

Polylogarithm and Riemann zeta  $\zeta(s) = \text{Li}_s(1)$  where  $\text{Li}_s(z) = \sum_{k \geq 1} z^k/k^s = (1/\Gamma(s)) \int_0^\infty t^{s-1} \mathrm{d}t/(\mathrm{e}^t/z - 1)$  obeys  $\text{Li}_{s+1}(z) = \int_0^z \text{Li}_s(t) \mathrm{d}t/t$  and  $\text{Li}_1(z) = -\log(1-z)$ . The dilogarithm obeys  $\text{Li}_2(x) + \text{Li}_2(1-x) = \pi^2/6 - \log(x) \log(1-x)$  (reflection formula) and  $\text{Li}_2(x) + \text{Li}_2(y) - \text{Li}_2(xy) = \text{Li}_2(t) + \text{Li}_2(u) + \log(1-t) \log(1-u)$  where x = t/(1-u) and y = u/(1-t) (pentagon formula).

Gauss hypergeometric function is given by  ${}_2F_1(a,b;c;z) = \sum_{n\geq 0} z^n(a)_n(b)_n/(n!(c)_n)$  converging for |z|<1, continued to  $\mathbb{C}\setminus [1,\infty)$  with branch cut. Here  $(a)_n=a(a+1)\dots(a+n-1)$ .

Generalized hypergeometric functions: let  $a_i, b_i \notin \mathbb{Z}_{\leq 0}$ . Then  ${}_jF_k(a;b;z) = \sum_{n\geq 0} z^n(a_1)_n \dots (a_j)_n/\big(n!(b_1)_n \dots (b_k)_n\big)$  converges if j=k+1 and |z|<1, or if  $j\leq k$ . Differential equation  $z\prod_{i=1}^j(z\partial_z+a_i)F(z)=z\partial_z\prod_{i=1}^k(z\partial_z+b_i-1)F(z)$ . Physically: vortex partition function of the 2d  $\mathcal{N}=(2,2)$  U(1) theory with j charge +1 and k+1 charge -1 chiral multiplets. Fox-Wright, Appell, Kampé de Fériet and Lauricella functions are vortex partition functions of specific U(1) $^n$  theories.

Basic hypergeometric series in terms of q-Pochhammer  $_j\phi_k(a;b;q,z)=\sum_{n\geq 0}\left(-q^{(n-1)/2}\right)^{n(1+k-j)}z^n(a_1,\ldots,a_j;q)_n/(b_1,\ldots,b_k;q)_n$ .

### §8.2 Physics of field theories

Phases characterized by potential V(R) (up to a constant) between quarks at distance R: Coulomb 1/R, free electric  $1/(R\log(R\Lambda))$ , free magnetic  $\log(R\Lambda)/R$ , Higgs (constant), confining  $\sigma R$ .

A solitary wave is a solution (of some wave equation) whose energy density is localized in space and travels at some speed u. A soliton additionally keeps its shape asymptotically after collisions.

Instantons are anti-self-dual  $(F = -\star F)$  connections on  $\mathbb{R}^4$  that decay at infinity and extend to  $S^4$ . The bundles are classified by  $\pi_3(G)$  so an instanton number  $k \in \mathbb{Z}$  for simple gauge groups; for fixed  $k \geq 0$  ( $k \leq 0$ ) (anti)instantons minimize the action. The k-instanton moduli space for  $G = \mathrm{SU}(N)$  is a 4Nk-dimensional [inspire:128223] hyperKähler manifold, in bijection with rank N framed locally free sheaves on  $\mathbb{CP}^2$  [inspire:125044].

**A** 't Hooft–Polyakov monopole is a smooth codimension 3 topological soliton where the gauge group G is spontaneously broken by a Higgs field to H, far from the soliton. Monopole charge is in  $\pi_2(G/H) = \operatorname{Ker} \left(\pi_1(H) \to \pi_1(G)\right)$  "Dirac monopole of H trivialized in G".

Example: SU(2) gauge theory with adjoint scalar  $\phi$  of potential  $(a^2 - \text{Tr }\phi^2)^2$ . Residual U(1) gauge field  $F_{\text{U}(1)} = \text{Tr}(\hat{\phi}F) - 2 \text{Tr}(\hat{\phi}D\hat{\phi}D\hat{\phi})$  with  $\hat{\phi} = \phi/\sqrt{\text{Tr }\phi^2}$  obeys  $\mathrm{d}F_{\mathrm{U}(1)} = \text{Tr}(\mathrm{d}\hat{\phi})^3$ , whose integral is the monopole charge.

# §8.3 Homotopy, homology and cohomology

**Basic properties.**  $\pi_0(X,x)$  is the set of connected components.  $\pi_1(X,x)$  is the fundamental group. For  $k \geq 1$ ,  $\pi_k(X,x)$  only depends on the connected component of x.  $\pi_k(X \times Y,(x,y)) = \pi_k(X,x) \times \pi_k(Y,y)$ .

**Quotient.** If G acts on connected simply-connected X then  $\pi_1(X/G) = \pi_0(G)$  (= G for G discrete).

Long exact sequence for a fiber bundle  $F \hookrightarrow E \twoheadrightarrow B$ : for base-points  $b_0 \in B$  and  $e_0 = f_0 \in F = p^{-1}(b_0) \subset E$ ,  $\cdots \to \pi_{i+1}(B) \to \pi_i(F) \to \pi_i(E) \to \pi_i(B) \to \cdots \to \pi_0(E)$  is exact, namely each image equals the next kernel (inverse image of the constant map).

Homotopy groups of spheres are finite except  $\pi_n(S^n) = \mathbb{Z}$  and  $\pi_{4n-1}(S^{2n}) = \mathbb{Z} \times \text{finite.}$  For k < n,  $\pi_k(S^n) = 0$ , and  $\pi_{n+k}(S^n)$  is independent of n for  $n \ge k+2$ . All  $\pi_k(S^0) = 0$ ,  $\pi_k(S^1) = 0$  for  $k \ne 1$ , and  $\pi_k(S^3) = \pi_k(S^2)$  for  $k \ne 2$ .

	$\pi_1$	$\pi_2$	$\pi_3$	$\pi_4$	$\pi_5$	$\pi_6$	$\pi_7$	$\pi_8$
$S^0$	0	0	0	0	0	0	0	0
$S^1$	$\mathbb{Z}$	0	0	0	0	0	0	0
$S^2$	0	$\mathbb{Z}$	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{12}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$
$S^3$	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{12}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$
$S^4$	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z} \times \mathbb{Z}_{12}$	$\mathbb{Z}_2^2$
$S^5$	0	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$

 $\pi_1(\mathbb{RP}^n) = \mathbb{Z}_2 \text{ for } n \geq 2 \text{ and } \pi_k(\mathbb{RP}^n) = \pi_k(S^n) \text{ for } k \geq 2.$  $\pi_1(\mathbb{CP}^n) = 0, \, \pi_2(\mathbb{CP}^n) = \mathbb{Z}, \, \pi_k(\mathbb{CP}^n) = \pi_k(S^{2n+1}) \text{ for } k \geq 3.$ 

Topological groups have abelian  $\pi_1(G)$ . Proofs. 1. The multiplication in G (point-wise) and concatenation of loops are two compatible group structures, hence (by Eckmann–Hilton theorem) coincide and are commutative. 2. Explicitly, for  $\alpha_1, \alpha_2 \in \pi_1(G)$  loops,  $(t_1, t_2) \mapsto \alpha_1(t_1)\alpha_2(t_2) \in G$  is a homotopy between  $\alpha_1 \star \alpha_2$  (concatenation) along bottom and right edges,  $\alpha_1 \cdot \alpha_2$  (point-wise multiplication) along the diagonal, and  $\alpha_2 \star \alpha_1$  along left and top edges.

 $H_k(\mathbb{CP}^n, M) = M$  for  $0 \le k \le 2n$  even, else 0.

### §8.4 Kähler 4-manifolds

K3 surfaces are (the only besides  $T^4$ ) compact complex surfaces of trivial canonical bundle. They have  $h^{1,0}=0$  (in contrast to  $T^4$ ). Their first Chern class  $c_1 \in H^2(X,\mathbb{Z})$  thus vanishes. By Yau's theorem there exists a Ricci flat metric, whose holonomy is then SU(2) = USp(2) by Berger's classification. K3 surfaces are thus Calabi–Yau  $(CY_2)$  and hyperKähler  $(hK_4)$ . Their moduli space is connected and they are all diffeomorphic.

**Examples of K3 surfaces.** Quartic hypersurface in  $\mathbb{P}^4$ . Kummer surface namely resolution of  $T^4/\mathbb{Z}_2$ .

Non-simply connected Ricci-flat Kähler manifolds may fail to be  $\mathrm{CY}_n$  when the restricted holonomy group is  $\mathrm{SU}(n)$  but the global holonomy group is disconnected. For example an Enriques surface  $\mathrm{K3}/\mathbb{Z}_2$  has a non-trivial canonical bundle.

A gravitational instanton is a metric with (anti-)self-dual curvature. A simply-connected Riemannian 4-manifold is hyper-Kähler if and only if it is a gravitational instanton. Compact hK<sub>4</sub> are K3 and  $T^4$ . Non-compact hK<sub>4</sub> are ALE (asymptotically locally Euclidean), ALF (asymptotically locally flat), ALG, ALH if their volume growth rate is of order 4, 3, 2, 1. ALE spaces are resolutions of  $\mathbb{H}/\Gamma$  for a finite subgroup  $\Gamma < \text{USp}(2)$ . The quotient  $\mathbb{H}/\Gamma$  can appear as a local model of an orbifold singularity in a K3 surface.

**ALE hyperKähler** 4-manifolds X are diffeomorphic to the minimal resolution of  $\mathbb{H}/\Gamma$  for some finite  $\Gamma \subset \mathrm{SU}(2)$ . The metric is fixed (up to isometry) by cohomology classes  $\alpha_1, \alpha_2, \alpha_3 \in H^2(X, \mathbb{R})$  such that there is no two-cycle  $\Sigma$  such that  $\Sigma \cdot \Sigma = -2$  and all  $\alpha_i(\Sigma) = 0$ .

# §8.5 Some algebraic constructions

The Weil algebra of a Lie algebra  $\mathfrak{g}$  is the differential graded algebra  $W(\mathfrak{g}) = \bigwedge^{\bullet} \mathfrak{g}^* \otimes S^{\bullet} \mathfrak{g}^*$ . Generators  $T^a \in \mathfrak{g}^*$  map to  $A^a \in \bigwedge^1 \mathfrak{g}^*$  of grading 1 and  $F^a \in S^1 \mathfrak{g}^*$  of grading 2. The differential obeys  $\mathrm{d} A^a = F^a - \frac{1}{2} f^a{}_{bc} A^b \wedge A^c$  and  $\mathrm{d} F^a = -f^a{}_{bc} A^b \otimes F^c \in \bigwedge^1 \mathfrak{g}^* \otimes S^1 \mathfrak{g}^*$  where f are structure constants of  $\mathfrak{g}$ .

Reduction of a Lie (super)algebra  $\mathfrak{g}$ . If  $\mathfrak{g} = V_1 \oplus V_2$  with  $[V_1, V_2] \subseteq V_2$  then the bracket of  $\mathfrak{g}$  restricted and projected to  $V_1$  defines a Lie (super)algebra.

S-expansion of a Lie (super)algebra  $\mathfrak{g}$  by an abelian multiplicative semigroup S: Lie (super)algebra  $\mathfrak{g} \times S$  with bracket  $[(x,\alpha),(y,\beta)]=([x,y],\alpha\beta)$ . If  $S=S_1\cup S_2$  with  $S_1S_2\subseteq S_2$  (in particular if there is a zero element  $0_S=0_S\alpha=\alpha 0_S$ ) then by reduction we get a Lie (super)algebra structure on  $\mathfrak{g}\times S_1$ .

**A color (super)algebra** is a graded vector space with a bracket such that (for X, Y, Z with definite grading)  $\operatorname{gr}[X, Y] = \operatorname{gr} X + \operatorname{gr} Y$  and  $[X, Y] = -(-1)^{(\operatorname{gr} X, \operatorname{gr} Y)}[Y, X]$  and Jacobi identity  $[X, [Y, Z]](-1)^{(\operatorname{gr} Z, \operatorname{gr} X)} + [Y, [Z, X]](-1)^{(\operatorname{gr} X, \operatorname{gr} Y)} + [Z, [X, Y]](-1)^{(\operatorname{gr} Y, \operatorname{gr} Z)} = 0$ , where  $(\bullet, \bullet)$  is some bilinear mapping into  $\mathbb{C}/(2\mathbb{Z})$ .

### §8.6 Other

A fuzzy space is d Hermitian matrices  $X^a$  ("coordinates") acting on some Hilbert space H. The dispersion of  $\psi \in H$  is  $\delta_{\psi} = \sum_{a} (\langle \psi | (X^a)^2 | \psi \rangle - \langle \psi | X^a | \psi \rangle^2)$ .
